UTM	Universal Transverse Mercator
VOC	Volatile Organic Compound

1.0 INTRODUCTION

Terrapex Environmental Ltd. (Terrapex) was retained by GFL Environmental Inc. (GFL) to prepare a combined geological and hydrogeological assessment for a property that GFL owns near the community of Moose Creek, Ontario. This report describes the existing geological and hydrogeological conditions in the on-site and off-site study areas in support of the GFL Eastern Ontario Waste Handling Facility (EOWHF) Future Development Environmental Assessment (EA). The regional location of the property is shown on Figure 1. The property includes the currently operating EOWHF (EOWHF Area) and an Expansion Area. The EOWHF Area includes an approved solid waste landfill site that is active and also hosts other waste management related activities. The Expansion Area is currently agricultural.

GFL plans to eventually expand waste deposition operations to the Expansion Area. GFL authorized this detailed study of geological and hydrogeological conditions as one of a wide range of studies required for the EA and for planning future development within the property.

The information and interpretations provided by this assessment will also be required by various levels of government and agencies for their review and approval of the application for the Expansion Area. The following governments and agencies have jurisdiction of the EOWHF Area and Expansion Area, as well as adjacent lands within 1.0 kilometre of the site:

- Township of North Stormont
- United Counties of Prescott and Russell
- United Counties of Stormont, Dundas and Glengarry
- South Nation Conservation Authority
- Government of Ontario (Ministry of the Environment, Conservation and Parks) (MECP).

2.0 SETTING

2.1 DEFINITIONS OF STUDY AREAS

Discussions herein are facilitated by defining several study areas, which are described below. The layouts of these areas are depicted in Figures 2 and 3.

- *On-Site Study Area*: For the purpose of the Environmental Assessment, the On-Site Study Area includes both the EOWHF Area and the Expansion Area, which are defined further below. It is situated on the majority (but not all) of Lot 13 and Lots 14 to 18 within Concession 10, in the Township of North Stormont, within the United Counties of Stormont, Dundas and Glengarry. It is bound on the west by agricultural land, on the east by Highway 138, on the south by Lafleche Road and various private properties, and on the north by Road 700, which is also known as Concession Road 7.
- *Off-Site Study Area*: Perimeter lands that are outside of the On-Site Study Area and within a 1.0 km radius of the On-Site Study Area boundary. The Off-Site Study area is located within both the Township of North Stormont in the United Counties of Stormont, Dundas, and Glengarry, and the Nation Municipality in the United Counties of Prescott and Russell. Given the nature of the soils in the vicinity of the site (fine-textured soils of silt and clay) which overlie limestone bedrock, the 1.0 km radius is suitable to evaluate hydrogeological conditions. The silt and clay soils are not present in the vicinity of a quarry to the east of the Expansion Area. The quarry is within the 1.0 km Off-Site Study Area.
- *EOWHF Area*: The western half of Lot 16 and Lots 17 and 18. The western portion of the On-Site Study Area hosts the approved EOWHF.
- *Expansion Area*: The majority (but not all) of Lot 13, Lots 14 and 15 and the eastern half of Lot 16. The eastern portion of the On-Site Study Area for which approval to develop for additional landfill capacity is being sought.

2.2 LOCATION AND DIMENSIONS

The nearest communities to the On-Site Study Area are Moose Creek, which is 4.9 km to the south and Casselman, which is 5.4 km to the west, as shown on Figure 1. The On-Site Study Area is located 58 km east of the City of Ottawa and 36 km northwest of the City of Cornwall, relative to urban centres. Locations and directions are approximate.

The On-Site Study Area essentially covers a quadrilateral wedge shape with sides of the following lengths: east is 1,705 m; west is 2,065 m; north is 2,750 m; and south is 2,315 m. Its area is 429 hectares. The EOWHF Area spans an essentially rectangular parcel of 925 m by 1,975 m covering 189 hectares. Relatively minor portions at the southeast and northeast corners are not part of the On-Site Study Area. See Figures 2 and 3 for the layout of the On-Site Study Area.

2.3 EXISTING AND LOCAL LAND USE

The EOWHF Area has official zoning of “Waste Disposal” and “Rural”. The expansion area has official zoning of “Agricultural” with a minor portion of Lot 13 that is zoned “Highway Commercial”.

The Off-Site Study Area has mixed zoning. It is mostly zoned as “Rural” or “Agricultural”. In the area east of the site, Lot 12 is zoned as “Employment District” and Lots 10 and 11 are a Licenced Pit Quarry. The area further to the west is zoned as “Agricultural”.

The On-Site Study Area is owned by GFL. The Off-Site Study Area includes multiple properties and parcels that are owned by the Province of Ontario (along Highways 138 and 417) and by assorted private individuals and commercial entities.

The current land use of the approved area of the On-Site Study Area is the Eastern Ontario Waste Handling Facility at 17125 Lafleche Road. The EOWHF includes closed waste cells, active waste cells, vacant cleared land and wooded areas (deciduous swamp and thicket swamp) that are planned to become waste cells, composting areas, internal roads, and diverse buildings for administration and operations. The current land use of the Expansion Area is agricultural, with crops including corn, soybeans and grass sod.

The current land uses within the Off-Site Study Area are diverse, and are characterised as follows.

- North: Primarily agricultural with crop farming. Highway 417 includes two lanes each for eastward and westward traffic. Road 700 and County Road 8 are two-lane roads. A single-family rural residence is located at 2251 County Road 8. A commercial property (Agro Culture 2001 Inc., Supreme Seeds Inc.) is located at 2311 County Road 8. A truck inspection station is located to the northwest along Highway 417.
- South: Primarily agricultural as grass sod farming. Lafleche Road is a two-lane road. A portion of the Moose Creek wetland is located in the extreme southwest, sometimes referred to as “Moose Creek Bog” on maps. To the southeast are commercial buildings for Champion Mushrooms Ltd. at 1434 Highway 138.
- West: Mostly agricultural lands with crops. To the northwest along Road 700 are two locations of rural-residential with agriculture and one location with a complex of agricultural buildings. Casselman Performance operates an all-terrain vehicle commercial operation at 49 Road 700.
- East: Primarily agricultural with diverse minor uses. Highway 138 and Allaire Road are two lane roads. Rural-residential style dwellings line Allaire Road. Also along Allaire Road are various commercial operations, including Larcorp Inc., Calco Soil, GFL Environmental, and Moose Creek Tire Recycling. The active Martin Quarry operated by A. L. Blair Construction Limited (Site ID 605082) and a possible former quarry exist along the north side of the road.

The above characterization is a summary. Other relatively minor land uses may also be present.

2.4 TOPOGRAPHIC RELIEF

Local topographic relief within the On-Site Study Area and the Off-Site Study Area is essentially a plain, descending in elevation toward the north. The average grade across the On-Site Study Area is approximately 0.2%. There are no distinct hills or valleys within the vicinity, although there are subtle and broad higher and lower areas that may affect local drainage patterns.

2.5 SURFACE WATER AND DRAINAGE

The On-Site Study Area and Off-Site Study Area are within the watersheds of Moose Creek and Scotch Creek, which are tributaries to the South Nation River that itself is tributary to the Ottawa River toward the north.

The On-Site Study Area and Off-Site Study Area have stormwater drained by a network of mostly linear ditches, termed “Drains”. Moose Creek flows toward the north, approximately 600 m to 850 m west of the EOWHF Area. The Fraser Drain runs along the northern and western boundaries of the On-Site Study Area and transects the EOWHF and Expansion Lands. The Upper Tayside Drain (also known as the Tayside-Legault Drain) runs within the interior of the southeastern part of the On-Site Study Area. This watercourse is tributary to the west branch of the Scotch River. See their alignments in Figure 3. Un-named drains and shallower ditches are also present along local roads and highways. Most of the On-Site Study Area is within the Moose Creek watershed.

Surface water generated within the EOWHF is managed internally, with grades and complex ditching feeding to storm water management ponds that release to the Fraser Drain.

The Expansion Area includes shallow ditches, spaced approximately 50 m apart and running in a south to north orientation, which feed into these drains, as observed in aerial photographs and provincial mapping. Flows are captured along a perimeter channel directly south of the Roxborough-Plantagenet Boundary Municipal Drain and flow westerly towards the Fraser Drain, and by the Upper Tayside Drain, which runs toward the northeast and discharges to the Scotch River.

Many features testify to poor natural drainage throughout the On-Site Study Area and Off-Site Study Area. Much of the Off-Site Study Area is mapped as being covered by organic deposits, as discussed in Section 2.6. The EOWHF Area was mapped as once being un-designated wetlands. The Moose Creek wetland is located to the southwest. A relatively dense network of ditches within the Expansion Area, as noted above, was necessary to promote drainage.

2.6 REGIONAL STRATIGRAPHY

The Off-Site Study Area and On-Site Study Area are mapped as being almost entirely covered by overburden deposits (Ontario Geological Survey, 2010). The overburden thickness varies from a few metres to approximately 30 m (MECP, 1997), where present.

The following main units are noted for the local region, in order of increasing depth (decreasing elevation). See Figure 4 that shows the distribution of geological units exposed at surface.

Organic. Deposits of peat, muck and marl. Covers the majority of the western, central and southern parts of the Off-Site Study Area and On-Site Study Area. Generally absent to the east and north.

Glaciomarine sediment. Generally fine-textured soils of silt and clay, with minor sand and gravel. Deposited by the post-glacial era Champlain Sea, which drained approximately 10,000 years ago. Covers the Off-Site Study Area and the On-Site Study Area, with the exception of an area to the east. Where present, thickness varies from a metre or so to approximately 20 metres.

Gravelly sand or sandy till. A bed of gravelly sand soils of variable description. Found below the glaciomarine sediment and above bedrock across the Off-Site Study Area and On-Site Study Area, although may be absent at some locations, leaving the glaciomarine sediment layer in direct contact with the underlying bedrock.

Bedrock. Limestone, sometimes with internal shale layers. Classified as the Lindsay Formation of the Simcoe Group, which dates to approximately the middle Ordivician era, i.e., approximately 450 million years old (Ontario Geological Survey, 2007). Its texture is sublithographic to fine crystalline, commonly nodular, with interbeds of calcarenite and shale (Ontario Geological Survey, 1985). The thickness of the Lindsay Formation is up to approximately 32.0 m. Shale interbeds may be present within the limestone and are up to 5 cm thick. Other bedrock layers / formations lie deeper than the Lindsay Formation. Bedrock is exposed or thinly covered over an approximately 100 hectare area that is east of Highway 138 and straddling north and south of Allaire Road.

2.7 REGIONAL HYDROGEOLOGY

2.7.1 STRATIGRAPHY

The main units described in Section 2.6 are anticipated to function as hydrostratigraphic units that are anticipated to provide distinct hydraulic properties. The units are discussed in order of increasing depth (decreasing elevation).

Organic. Partially saturated where shallow, saturated at depth. Variable hydraulic conductivity, with decreasing values at greater depth due to compaction. Likely to function as an unconfined aquifer.

Glaciomarine sediments. Saturated. Very low hydraulic conductivity, with variation due to soil fractures. Likely to function as a regional aquitard due to low hydraulic conductivity and relatively significant thickness. Likely to produce a limited groundwater yield when used for domestic water supply.

Gravelly sand or sandy till. Saturated. Moderate to relatively high hydraulic conductivity, with variation. Likely to function as a confined aquifer.

Bedrock. Saturated. Low to relatively high hydraulic conductivity, with variation due to fracture aperture (width) and density. Likely to function as a confined aquifer where more highly

fractured - usually in the upper few metres of bedrock. At some locations the bedrock exhibits sparse fracture spacing and at depth it is unweathered featuring fewer fractures and tighter fracture apertures.

Vertically-oriented fractures in the upper bedrock are apparent in an aerial image (Google Earth Pro, 2016) of the yard of 17305 Allaire Road, which is within 100 m of the On-Site Study Area. The fractures appear to be clustered in two main preferred orientations and spacings, as follows.

- Oriented 110°/ 290° with spacing of approximately 1 to 2 m
- Oriented 75°/ 235° with spacing of approximately 4 to 7 m

The above-indicated orientations are approximate, with variance of +/- 10° . Fractures in other orientations occur in this outcrop, either as individual outliers or as sets. In addition, there will also be horizontally-oriented fractures and partings reflecting internal layers, bedding planes and other structures.

Regionally, groundwater movement trends toward the north or northwest (Map 2200. Ministry of the Environment, 1997).

2.7.2 GROUNDWATER QUANTITY

Aquifers are hydrostratigraphic units that are capable of yielding significant quantities of water to a supply well.

The glaciomarine sediment layer is likely to produce a limited groundwater yield.

The sandy gravel layer below the glaciomarine sediment and above the bedrock can function as an aquifer where its thickness is more than a few metres and contains relatively lower fine fractions.

The limestone bedrock provides an extensive aquifer in the South Nation River basin (Ministry of the Environment, 1997). Relatively higher transmissivity is anticipated in the upper-most horizon of the bedrock. Wells screened in this aquifer have a sufficient quantity for domestic uses but not higher yields.

In general, the basal gravelly sand and the upper horizon of bedrock, with its more intense fracturing function, is the zone where there is preferential groundwater flow on a regional basis (Colgrove, 2016).

2.7.3 GROUNDWATER QUALITY

Groundwater in the limestone is sometimes noted as often being highly mineralized, including to a saline condition.

Groundwater in Champlain Sea sediments can be highly mineralized, including to a saline condition. Elevated total dissolved solids, sodium, halogens (chloride, fluoride, iodide) and methane are encountered (Colgrove, 2016).

Bedrock topography may influence the groundwater quality. At locations of thinner overburden due to higher bedrock, fresher quality recharge waters more easily reach the elevated bedrock and mix with overburden groundwater. Where bedrock is at a lower elevation and overburden is correspondingly thicker, chemical processes such as ion exchange, diffusion and porewater expulsion are promoted, which increase ion concentration and alter ion chemistry. Advanced organic decomposition that produces more methane and hydrogen sulphide occurs most strongly in major bedrock depressions capped by thicker glaciomarine clays (Colgrove, 2016).

Some local water supply wells in the MECP water well database report sulphurous odours.

2.8 LOCAL GROUNDWATER SUPPLIES

There are no municipal piped water supplies in the On-Site Study Area and the Off-Site Study Area. Each property is likely serviced by a private supply well, with the possibility of some relying on bottled water. The presence and distribution of groundwater supply wells was assessed using the following two primary sources of information.

- MECP water well database. This database consists of well information as reported by local drilling contractors and as recorded by MECP staff. It contains information on well construction, stratigraphy and other aspects, in varying detail. A copy of the listings is provided in Appendix III.
- Aerial photographic analysis. Water supply wells are assumed to be situated near to occupied buildings that are being supplied, such as a residence or a commercial operation.

The private wells determined by these methods are mapped on Figure 5. This map shows wells located within the On-Site Study Area, the Off-Site Study Area and an area beyond the Off-Site Study Area but where public perception should be considered due to likely being downgradient.

The following distribution of water supply wells was noted within the Off-Site Study Area and the On-Site Study Area. The relative position with respect to the direction of groundwater movement is also provided.

- Within EOWHF Area: 1. Upgradient of waste cells.
- Within Expansion Area: 0 / None
- Western part of Off-Site Study Area: 3. Cross-gradient of expansion area.
- Southern part of Off-Site Study Area: 0 / None
- Southwest and western part of Off-Site Study Area. 1 (One). Upgradient of expansion area.
- Eastern part of Off-Site Study Area. 17. Cross-gradient of expansion area.

- Northern part of Off-Site Study Area. 6. Downgradient.
- Northern area beyond 1.0 km from Off-Site Study Area: 12. Downgradient.

Some of the wells interpreted from the presence of an occupied building(s) may be the same wells as recorded in the MECP database, so are treated as a single location on the map. Based on the above, there are possibly 27 private supply wells in the Off-Site Study Area and approximately 12 wells located further north.

The MECP water well database within the Off-Site Study Area indicated the majority of the wells had a supply purpose – domestic, livestock, irrigation, commercial and/or industrial.

A portion of the Ste. Rose de Prescott Aquifer is mapped as incurring within the northern fringe of the Off-Site Study Area (MECP, 1997).

The above data should be considered a preliminary understanding with uncertain reliability. For example, recently constructed wells in the MECP database include locations measured by a GPS device with more reliable location accuracy, while older wells in the MECP database are sometimes based on a rough hand sketch, so positions have reduced confidence. It is possible that some listed wells may be abandoned or are no longer in use. There may be some more recently constructed wells reported by drillers that are not yet updated to the database by government staff. The assumed placement on occupied properties may be located with different actual locations.

2.8.1 SIGNIFICANCE OF GROUNDWATER RESOURCES

Groundwater resources are significant for providing a number of functions. Groundwater discharge provides baseflow of local watercourses, it provides discharge to regional wetlands, and it replenishes aquifers used as a supply for drinking and for a range of agricultural, industrial and commercial purposes.

The site is within the larger area administered by the Raisin-South Nation Source Protection Region, which is the government agency charged with groundwater protection.

The On-Site Study Area and Off-Site Study Area were reviewed within mapping of sensitive areas of the Source Protection Atlas (2020). Mapping indicates that most of the On-Site Study Area and a significant portion of the Off-Site Study Area south of Highway 417 are classified as a Significant Groundwater Recharge Area with a score of 6. Also, most of the On-Site Study Area and a significant portion of the Off-Site Study Area south of Highway 417 are classified as a Highly Vulnerable Aquifer with a score of 6. Sensitive groundwater areas are shown on Figure 6.

The Raisin-South Nation Conservation Authority was contacted with respect to requirements or restrictions on potential activities due to these classifications. The On-site Study Area has not been identified as a well head protection area (WHPA) or intake protection zone (IPZ). With respect to Source Protection Plans within the Raisin Region Source Protection Area and South Nation Source Protection Area, only WHPAs and IPZs are subject to the prohibition of specific

activities or subject to Risk Management Plans. The designation of On-site and Off-site Study Areas as a Significant Groundwater Recharge Area or a Highly Vulnerable Aquifer do not lead to prohibitions of activities or Risk Management Plans.

2.8.2 USES OF GROUNDWATER RESOURCES

Water supply wells within the Off-Site Study Area include the following categories with typical associated common purposes. Other purposes are possible.

- Domestic: for drinking, cooking, washing
- Commercial: for drinking, washing
- Livestock: for provision of drinking supplies to livestock animals
- Irrigation: for crops
- Industrial: for washing of aggregate, landfill operations, dust suppression

A search for Permits to Take Water in the provincial government database indicated one listing of No. 0431-AHNHVJ, having the purpose of pits and quarries. Its maximum allowable taking of groundwater and surface water is 1,182,816 litres per day.

2.9 SENSITIVE ENVIRONMENTAL FEATURES AND CLASSIFICATIONS

There are no sensitive environmental features mapped as being downgradient of the Off-Site Study Area or On-Site Study Area. The Moose Creek wetland (also known as the Moose Creek bog) that is southwest of the On-Site Study Area is interpreted to be upgradient.

There are no additional Areas of Natural and Scienific Interest (ANSI), Provincially Significant Wetlands (PSWs), undesignated wetlands or undesignated / designated woodlands within the Off-Site Study Area or On-Site Study Area.

The Fraser Drain and the Upper Tayside Drain are tributaries to natural watercourses.

2.10 CLIMATE

The climatic conditions were measured at the climate station located at the St. Albert weather station. The reported values are based on the 30 year monthly averages between 1981 to 2010. The climate station is approximately 11 km to the southwest and has an elevation of approximately 65 masl compared to the site's approximate elevation of 68 masl.

The monthly average temperatures range from -10.2 °C in January to 20.3 °C in July. The monthly average precipitation ranges from 59.8 mm in February to 103.3 mm in September, with an annual total of 1055 mm/year.

3.0 METHODOLOGY

The following describes the methodology and locations of investigation in the field program at the potential expansion area to the east and replacement wells in the EOWHF Area installed during 2020.

3.1 DRILLING

A program of drilling for combined hydrogeological and geotechnical purposes was performed in the potential expansion area to the east between January 21 and February 7, 2020. Replacement monitoring wells and new installations L6, L7, MW96-5AA and MW96-6Ar were completed on the EOWHF between February 10 to 19, 2020 and November 3 to 6, 2020. Monitoring wells to the south of the EOWHF were completed between November 1 and 6, 2020. The drilling contractor and crew were licensed in accordance with the Ontario Water Resources Act R.R.O. 1990, Regulation 903 (Wells), last amendment O. Reg. 389 / 09.

Drilling was performed at eighteen (18) locations with broad distribution across the potential expansion area to the east. Locations are designated as MW20-1 through MW20-12, MW20-15, MW20-17 and MW20-18. Installations at BH20-13, BH20-14 and BH20-16 were boreholes, not completed as monitoring wells. The suffix “S” represents a monitoring well screen completed within shallow clay (e.g., MW20-1S); “C” represents a monitoring well screen completed in deeper clay (e.g., MW20-2C); “T” represents a monitoring well screen completed in till above bedrock (e.g., MW20-1T); and, “D” represents a well screen completed within bedrock (e.g., MW20-1D).

The monitoring wells installed to the south of the EOWHF are designated MW20-19 and MW20-20. At these locations, the “A” horizon represents screens installed within bedrock; the “B” horizon screens are installed within till above the bedrock; the “C” horizon well screens are installed within deeper clay, and the “D” horizon monitoring well screens are installed within shallow clay.

Monitoring wells L6 and L7 were installed at the southern limit of the EOWHF property within shallow silty clay. Replacement monitoring wells, identified by the suffix “R” are screened at the same intervals as the wells that they replace (S1-1A-R, S1-1B-R, S1-3A-R, P1-3B-R). Monitoring wells MW96-5AA and MW96-6A were competed within bedrock adjacent to the existing monitoring wells MW95-5C and MW96-6B/MW96-6D.

Borehole logs for the newly installed monitoring wells are included in Appendix A.

The boreholes were advanced using rotary methods. In overburden, the drill casing was coupled to a drilling bit. Bedrock coring methods are described in Section 3.2. The cuttings produced were transported to the surface by water and left on an adjacent snow-covered field. The water used in drilling was sourced from the on-site supply well that is in the southern part of the EOWHF Area.

Three of the drilling locations had boreholes with no monitoring well; these boreholes were backfilled with bentonite upon completion.

Soil samples were collected, generally at 1.5 m intervals, using a split spoon device. These samples were described, then placed in sealed airtight plastic bags. Descriptions included texture, colour, moisture, and structure. Soil samples were logged in the field by the qualified geo-environmental technician, then confirmed by a Professional Engineer at Terrapex's Ottawa facility.

Soil samples were not collected from the shallower boreholes of well cluster locations, with reliance on soils recorded in the nearby deepest borehole. At some locations, the borehole's purpose was to establish the depths of stratigraphic interfaces by inference of drilling resistance, with no soil samples recovered. The base of glaciomarine sediment / top of till interface was inferred by the marked increased resistance to soil drilling and the top of bedrock was inferred by refusal to the soil drilling.

Standard penetration tests (SPT) were periodically performed while advancing the boreholes in the soils to take representative samples and to measure penetration index (N-values). The N value reflects the number of blows of a standard striking hammer that were required to drive the split spoon sampler down by 300 mm. The values are presented in the borehole records. Additional geotechnical borehole tests were also conducted, which are described in the companion geotechnical report (Terrapex, 2021).

The silty clay unit was also sampled by means of a thin walled tube (Shelby Tube) in the boreholes for MW20-2D, MW20-3D, MW20-8D, MW20-9D, MW20-10D and MW20-11D. This method yields relatively undisturbed samples for laboratory analysis and testing.

3.2 BEDROCK CORING

Bedrock within the Expansion Area to the east was cored at twelve (12) locations using rotary drilling methods with a diamond drill bit of NQ size (i.e., 76 mm outer diameter). Core samples were recovered with an average length of 3.0 m, ranging from 2.5 m to 6.1 m. Bedrock wells were also installed south (MW20-19A) and within (MW96-5AA and MW96-6A1) the EOWHF.

Water required for the rotary drilling equipment was sourced from a water well located in the EOWHF Area. The well is upgradient of the waste fill areas. Water was pumped from the well to a GFL water tanker truck, transferred to a secondary water truck provided by the drilling contractors, then to the borehole.

Rock cores were described in the field by the observing technician for lithology, rock quality designation (RQD), total core recovery (TCR), fractures, weathering, voids and other characteristics. Following description, cores were sealed in wooden core boxes and brought to Terrapex's laboratory in Toronto for review by the Senior Hydrogeologist.

3.3 MONITORING WELL INSTALLATIONS

Monitoring wells were installed for the purposes of testing hydraulic conductivity, for sampling groundwater quality and for measurement of piezometric levels. Monitoring wells within the Expansion Area were installed at fourteen locations over a broad geographic distribution. Most

locations were clusters of monitoring wells with two or three wells, with each well installed in a separate borehole, within approximately 2 m of adjacent wells of the cluster. A few locations consisted of a single well.

The monitoring wells were constructed using 50 mm diameter, Schedule 40, PVC, environmental-grade riser piping with machine slotted (10 slot) screens with an open length of 1.5 m at the bottom. The boreholes were backfilled with sand to approximately 0.3 m above the screened interval and then sealed above with bentonite to surface. The PVC pipe had a j-plug to prevent contamination. The monitoring wells were completed with an above-grade casing protector with locked lid.

The monitoring well screens installed at each location within the Expansion Area were placed in the following vertical pattern, which was based on stratigraphy. See Figure 3 for well locations. The wells were designated in the MW20-# series, with suffix (noted below) indicating the stratigraphic screen position.

- Shallow wells. Designated with an ”S” suffix. Thirteen such wells were installed. Objective was to determine the water table. The bottoms of screens were installed in the range of 3.8 to 4.2 metres below grade (mbg).
- Clay with silt wells: Designated with a ”C” suffix. Seven such wells were installed. Objective was to determine conditions within the glaciomarine deposit at a relatively consistent depth range. The bottoms of screen were installed in the range of 6.9 to 7.6 mbg.
- Sandy Till wells: Designated with a ”T” suffix. Five such wells were installed. Objective was to determine conditions within the till. The bottoms of screen were targeted to provide a vertical set back of a few metres above the bedrock interface, if the till layer was sufficiently thick. The bottoms of screen were installed in the range of 6.0 to 17.0 mbg, which varied with the position of the till / bedrock interface.
- Bedrock wells: Designated with a ”D” suffix. Twelve such wells were installed. Objective was to determine conditions within the bedrock. The bottoms of screen were targeted to have a setback of at least 1 to 2 metres below the overburden to avoid interference by overburden. The bottoms of screen were installed in the range of 9.1 to 25.5 mbg, which varied with the position of the top of bedrock.

This assessment of hydrogeological conditions of the On-Site Study Area also incorporates monitoring wells installed within the EOWHF area. EOWHF wells include clusters in the MW96-# series. The well clusters have the following suffix conventions: A = bedrock well; B = till well; C= clay well; and D = shallow well.

The well components and their relationships to adjacent stratigraphy are shown in the well records provided in Appendix III and their dimensions are reported in Tables 1 and 2.

Monitoring wells in the EOWHF Area should be maintained as part of the long-term monitoring program. Monitoring wells in the Expansion Area should be retained for long-term monitoring of conditions prior to construction and during the operational period of the Expansion Area, once

approved and active. The necessity for retaining monitoring wells should be reviewed on an annual basis by a hydrogeologist and GFL. If one or more monitoring wells are determined to be no longer useful or are damaged, then they must be abandoned by a licensed water well contractor. Damaged wells can be replaced or abandoned, pending discussion with a hydrogeologist and GFL. Abandonment must proceed in accordance with Regulation 903 and amendments issued under the Ontario Water Resources Act.

3.4 MONITORING WELL DEVELOPMENT

Monitoring well development was required to remove standing water in the monitoring wells and to remove the remaining portions of water necessarily injected into the borehole to facilitate drilling. Development was undertaken following Terrapex's Standard Operating procedures. The development proceeded soon after construction, during 25 February to 31 March 2020. Water was pumped using dedicated low density polyethylene (LDPE) tubing, equipped with a LDPE foot valve, for each monitoring well.

The monitoring wells exhibited variations in ability to provide water and the degree of recovery to likely static levels. Some wells were purged of the volume of water in the pipe riser and screen zone plus the estimated amount in the annular sand pack zone. Some wells were purged to a nearly dry condition, then allowed to recover, which was repeated for three cycles. Some wells were purged of one volume to dry but did not recover more than a few centimetres of water.

3.5 WATER LEVEL MEASUREMENTS

Groundwater levels were measured in the MW20-series monitoring wells of the Expansion Area on 26 February, 5 March, 8 April, 13 May and 8 June 2020. The groundwater levels and elevations measured on these dates are presented on Table 5. Levels were measured by an electric sounder device with a graduated tape. Additional measurements were obtained during sampling and for other isolated events.

Groundwater levels at all accessible monitoring wells were measured on 15 November 2020, 10 May and 3 August 2021. The groundwater levels and elevations measured on these dates are presented on Table 6.

3.6 GROUNDWATER SAMPLE COLLECTION

Groundwater sampling events were conducted during 5 to 9 March 2020 and during 8 to 11 June 2020 in the monitoring wells located east of the EOWHF. Groundwater was sampled using “low-flow” methodology with a peristaltic pump in accordance with Terrapex's Standard Operating procedures (SOPs). Groundwater was discharged directly into pre-cleaned, laboratory-supplied bottles, placed in a cooler with ice, and shipped under chain of custody to the Eurofins Experchem Laboratories Inc. (Eurofins) branch in Ottawa, Ontario. The laboratory conducted analysis for a broad spectrum of parameters, generally corresponding to Schedule 5 - Comprehensive List for Groundwater and Leachate from the MECP’s Landfill standards: A guideline on the regulatory and approval requirements for new or expanding landfilling sites (Landfill Guideline). The full list

of parameters analysed in March and June 2020 are shown on the results table presented in Appendix II.

Groundwater samples were collected in the Fall of 2020, Spring of 2021 and Summer of 2021 from all monitoring wells between 25 November and 1 December 2020, between 11 and 13 May 2021 and between 3 and 6 August 2021. Samples were analysed by Eurofins for the parameters identified in "List A" of Schedule "D" of ECA No. A420018, which generally comprise Schedule 5 – Indicator List for Groundwater and Leachate from the Landfill Guideline (with the addition of biological oxygen demand (BOD)). The full list of parameters analysed in November 2020 and in May and August 2021 are shown on the results table presented in Appendix II.

3.7 HYDRAULIC CONDUCTIVITY TESTING

Hydraulic conductivity was assessed using a variety of methods, including single well response tests, the Hazen formula based on grain size analysis, laboratory permeameter tests, and consolidation tests. The wells tested, representative depths and methods are listed on Table 4.

Single well response tests consisted of a bail test, which involved a rapid removal of a volume of water using an elongated bailer, then observing the rising recovery to static level over time. These tests were performed in MW20-1T, MW20-3D, MW20-4D, MW20-4C, MW20-5T, MW20-6D, MW20-6S, MW20-7C, MW20-8C, MW20-8S, MW20-9T, MW20-10D, MW20-11C, MW20-11S, MW20-12S and MW20-15T. Water level measuring dataloggers were used to supplement water level measurements at most test wells. A barometric logger was installed on Site to allow removal of air pressure effects from the levelogger record. Observations were analysed using the Aqtesolv software package by the Bouwer and Rice method.

The Hazen formula method is applicable for soils having a texture that is dominantly silt or coarser. The d_{10} value is used, which is the grain size diameter below which is 10% of the sample, by weight. Sufficiently coarse textured samples for which grain size analyses were conducted include MW20-3D Sample 12, MW20-5D Sample 5B, MW20-5D Sample 7 and MW20-9D Sample 10. Other samples for which grain size analysis was performed were too fine for application of this formula.

Laboratory permeameter testing involves compacting a clayey soil sample into a cylinder, and then passing water through in a prescribed protocol. The tests were conducted by Terrapex's geotechnical laboratory on silty clay from MW20-1D, MW20-4D, MW20-5D, MW20-6D and MW20-9D.

One-dimensional consolidation tests are conducted on thin-walled tube ("Shelby tube") samples of relatively undisturbed samples of silty clay, which yield permeability values that can be converted to hydraulic conductivity values. Such tests were performed on samples from MW20-2D, MW20-3D, MW20-8D, MW20-9D, MW20-10D, and MW20-11D.

3.8 QUALITY ASSURANCE AND QUALITY CONTROL

Field staff assigned to this project were properly trained and equipped. All field equipment was confirmed to be in good working order and properly calibrated, which were documented. Field tasks were conducted in accordance with standard operating procedures (SOPs).

Field reports were reviewed for accuracy by the field technician, the project manager, and by a senior Professional Geoscientist (P.Geo.) or senior Professional Engineer (P.Eng.).

Eurofins Environmental Testing Canada Inc. (Eurofins) is accredited by the Standards Council of Canada (SCC), the Canadian Association for Laboratory Accreditation (CALA), and operates in accordance with ISO 17025:2005. Eurofins is licensed by the Ontario Ministry of the Environment, Conservation, and Parks (MECP) for specific tests in drinking water (License #2318).

Eurofins conducts its own routine internal Quality Assurance/Quality Control (QA/QC) program that consisted of the analysis of laboratory replicates, process and method blanks, process percent recoveries, matrix spikes, method spikes and surrogate percent recoveries, as appropriate for the particular analysis protocol.

Terrapex also submitted four field duplicate samples that were known to Terrapex but not by the laboratory. These were labelled by Terrapex as Dup 1 through to Dup 4 that were duplicates of samples MW20-1T, MW20-7D, MW20-8C and MW20-10S, respectively. The duplicate QA/QC samples were consistent with the results for the original samples.

Trip blanks, field blanks, and trip spikes measured Volatile Organic Compounds (VOC's) were used to confirm that sampling handling and transport did not contaminate the samples. The trip blanks and the field blanks had VOCs indicated concentrations below the method detection limits. The trip spikes recovered concentrations between 59 to 139% of the original concentration, which indicates that VOC concentrations reported by the laboratory are reliable indicators of actual presence in the groundwater, where measured above the detection limit.

3.9 SURVEYING AND LOCATION CONTROL

An elevation and location survey of the MW20-series clusters within the Expansion Area and of nearby EOWHF Area monitoring well clusters (MW96-1, MW96-2A and MW96-3) was conducted on 27 February 2020. The survey instrument used was a Topcon Hiper V GNSS Receiver with centimetre-scale accuracy.

4.0 INTERPRETATION

4.1 TOPOGRAPHY AND SURFACE WATER COURSES

The On-Site Study Area and the Off-Site Study Area occupy a plain descending northward, as discussed in Section 2.4. There are no naturalized surface water courses within the On-Site Study Area. As discussed in Section 2.5, networked systems of anthropogenic drains / ditches are constructed within and adjacent to the On-Site Study Area. These include the named watercourses of the Fraser Drain, the Albert Fahey Award Drain and the Upper Legault Drain that are tributary to the Moose Creek and Scotch River watersheds. The entirety of the EOWHF Area and most of the Expansion Area are part of the Moose Creek watershed. Only a minor portion on the east side of the Expansion Area close to the Upper Legault Drain is part of the Scotch River watershed (Sabourin, 2017).

4.2 WATER TABLE

Groundwater levels observed in monitoring wells are provided on Tables 5 (Spring 2020) and 6 (Fall 2020, Spring 2021 and Summer 2021).

Groundwater contours are presented for the Fall 2020, Spring 2021 and Summer 2021 monitoring events. Piezometric contours are presented on Figures 7A1/7A2/7A3 (Bedrock), Figures 7B1/7B2/7B3 (Silty Clay) and Figures 7C1/7B2/7C3 (Shallow Clay). Because the till is not continuous across the site, piezometric elevations in the till layer are not shown. The till and underlying bedrock are generally hydraulically interconnected.

As shown on Figures 7A1/7A2/7A3, groundwater flow in bedrock is generally northward. Figures 7B1/7B2/7B3 and 7C1/7C2/7C3 illustrate effects of groundwater mounding below the completed landfill. Shallow groundwater below the potential expansion area to the east of the EOWHF does not show mounding effects (refer to Figure 7B1/7B2/7B3).

The water table in the Expansion Area is indicated by groundwater levels observed in the monitoring wells with screens shallower than approximately 4.5 mbg. The observations during April to June 2020 likely reflect static water levels without influence of well development and/or sampling and likely approach the maximum elevation that would occur in an annual cycle, pending long-term observations. The water table depth during the above-noted period ranged from 0.5 mbg to 1.7 mbg, with an average of 1.1 mbg. The shallowest depth was 0.3 mbg in MW20-4 near to the southern boundary of the Expansion Area in January 2020.

Piezometric elevations reflect groundwater pressures at greater depth and may not necessarily correspond to the water table.

Groundwater levels naturally fluctuate in response to seasons, annual variations and major storm events. The range of annual fluctuation in shallow groundwater is also likely to vary by location. Typically, the water table is at the lowest elevation (greatest depth) phase during later summer to early autumn. Typically, the water table is at highest elevation (shallowest depth) phase during

later winter and early spring. Groundwater could rise to slightly higher elevations during a wetter year or season as compared to the observations thus far.

4.3 SUBSURFACE AQUIFERS

An aquifer can be defined as a soil or bedrock horizon capable of providing a useful quantity of water, which is usually a domestic supply. Potential aquifers underlying the On-Site Study Area include the gravelly sand till layer and the upper horizon of bedrock where relatively more fractured. Most local supply wells in the Off-Site Study Area are completed in reported sandy gravel units that likely correspond to the till layer or into bedrock in the On-Site Study Area. Hydraulic continuity between the sandy gravel till and shallow bedrock within the On-Site Study Area and aquifers in the Off-Site Study Area is not established.

The silty clay layer is generally incapable of serving as an aquifer due to its low intrinsic hydraulic conductivity.

The southern portion of the area mapped as the Ste. Rose de Prescott aquifer crosses into the Off-Site Study Area. This aquifer is approximately 800 m beyond the On-Site Study Area, as shown on Figure 6. The aquifer is described as being a confined overburden unit, but no other details were available (MECP, 1997). Selected water well records in the MECP database mapped as within this aquifer tap into the gravelly sand till unit, which is above the bedrock and below the glaciomarine silty clay.

4.4 INTERCONNECTIONS BETWEEN AQUIFERS

The gravelly sand till directly rests on the fractured, more upper portion of underlying bedrock at most locations within the On-Site Study Area. Both horizons offer relatively higher hydraulic conductivity, which will facilitate hydraulic interconnection.

The vertical hydraulic gradient between bedrock and the overlying gravelly sand till was, as measured in 2020, upward at MW96-1, MW96-2, MW20-5 and MW20-9. The magnitude of the upward gradient ranged from 0.001 to 0.015 m/m. The vertical hydraulic gradient varies between being upward and downward at MW20-1 and MW20-6, depending on the date. The magnitude of the gradient at those wells ranges from 0.007 m/m downward to 0.04 m/m upward. These ranges exclude those dates when the monitoring wells were interpreted to be still recovering from development or sampling.

In the contingency that leachate were to migrate through the silty clay layer to reach the underlying more permeable glacial till layer, groundwater would then move horizontally through the till and connected upper bedrock. There could be complex upward and downward exchange between the till layer and the upper fractured bedrock due to variations in hydraulic conductivity of both units and presence of the till.

4.5 GROUNDWATER QUALITY

Laboratory groundwater quality results from the groundwater sampling events conducted in March, June and November/December 2020 and May, August and November 2021 were compared to criteria of the Ontario Drinking Water Quality Standards of Regulation 169/03 under the Safe Drinking Water Act; Ontario Drinking Water Standards, Objectives and Guidelines (June 2006) and the MECP Table 2 SCS in a Potable Ground Water Condition of Regulation 153/04 under the Environmental Protection Act.

Groundwater sampling during the March and June 2020 sampling events took place on the monitoring wells installed in the eastern Expansion Area. The November/December 2020 and May, August and November 2021 groundwater sampling events were conducted across the Expansion Area and EOWHF Area. Concentrations of tested parameters as reported by the laboratory for the samples are provided in Appendix II.

Alkalinity, hardness, total dissolved solids (TDS), chloride and dissolved organic carbon (DOC) are often used as indicator parameters for leachate. The concentrations of these parameters are mapped on Figures 8A1/8A2/8A3/8A4 (Bedrock wells Fall 2020/Spring 2021/Summer 2021/Fall 2021), 8B1/8B2/8B3/8B4 (Silty Clay wells Fall 2020/Spring 2021/Summer 2021/Fall 2021) and 8C1/8C2/8C3/8C4 (Water Table wells Fall 2020/Spring 2021/Summer 2021/Fall 2021) through Figures 12A1/12A2/12A3/12A4, 12B1/12B2/12B3/12B4 and 12C1/12C2/13C3/13C4, respectively.

Alkalinity (Figures 8A1/8A2/8A3/8A4, 8B1/8B2/8B3/8B4 and 8C1/8C2/8C3/8C4). Operational Guideline (ODWO = 500 mg/L)

Elevated alkalinity in bedrock is expected as a background condition within limestone bedrock. Variations in alkalinity concentrations within bedrock are not anticipated to result from landfill operation.

Elevated alkalinity in the deeper silty clay at MW96-3B (Figures 8B1/8B2/8B3/8B4) and shallow silty clay at MW96-3C (Figures 8C1/8C2/8C3/8C4) show continuation of an increasing trend noted by Tetra Tech in 2019 (Tetra Tech 2019 Annual Report). Tetra Tech concluded in their 2020 Annual Report that MW96-3B and MW96-3C do not appear to be impacted by leachate. Tetra Tech further indicates that MW96-1D is likely impacted by surface water infiltration versus direct leachate impacts.

Hardness (Figures 9A1/9A2/9A3/9A4, 9B1/9B2/9B3/9B4 and 9C1/9C2/9C3/9C4) Operational Guideline (ODWO = 80 to 100 mg/L)

Hardness (as $CaCO_3$) is a measure of calcium and magnesium hardness, calculated as:

Hardness (mg/L) = $2.5\ (Ca^{2+}) + 4.1\ (Mg^{2+})$

Elevated hardness in bedrock is expected as a background condition within limestone bedrock. Variations in hardness concentrations within bedrock are not anticipated to result from landfill

operation. As shown on Figures 9A1 through 9A4, with the exception of MW96Ar, hardness is highest at the eastern limit of the potential expansion area to the east of the EOWHF.

Elevated hardness in deeper silty clay (Figures 9B1 through 9B4) and shallow clay (Figures 9C1 through 9C4) shows continued trends from 2019. Previous reports by TetraTech interpreted that these continued trends were not related to leachate impacts, but to historical background values.

The elevated concentrations of alkalinity, hardness, total dissolved solids, chloride and dissolved organic carbon at the southeastern limit of the EOWHF in bedrock in the Summer and Fall 2021 (MW96-6Ar; Figures 8A3/8A4, 9A3/9A4, 10A3/10A4, 11A3/11A4 and 12A3/12A4) appear unrelated to the EOWHF, as these elevated parameters are not evident in the overlying silty clay or shallow wells. These elevated parameters observed in bedrock in MW96-6Ar are reflective that groundwater in the regional limestone aquifer is sometimes noted as often being highly mineralized, including to a saline condition.

Total Dissolved Solids (TDS; Figures 10A1/10A2/10A3/10A4, 10B1/10B2/10B3/10B4 and 10C1/10C2/10C3/10C4). Aesthetic Objective (ODWO = 500 mg/L)

Elevated TDS in bedrock (Figures 10A1 through 10A4) is expected as a background condition within limestone bedrock.

Elevated TDS in the deeper silty clay (Figures 10B1 through 10B4) appears independent of landfill impacts; elevated values are a result of natural variation in the clay, as demonstrated by the highest concentrations observed south and east of the EOWHF.

Elevated TDS within shallow silty clay (Figures 10C1 through 10C4) is influenced by the leachate holding ponds in the north and aeration ponds in the south.

Chloride (Figures 11A1/11A2/11A3/11A4, 11B1/11B2/11B3/11B4 and 11C1/11C2/11C3/11C4). Standard (ODWO = 250 mg/L)

Elevated chloride in bedrock is localized, and likely results from the historic depositional environment. The distribution of chloride in bedrock is unrelated to chloride in deeper silty clay (Figures 11B1 through 11B4) and shallow silty clay (Figures 11C1 through 11C4), both of which demonstrate no significant impact.

Dissolved Organic Carbon (DOC; Figures 12A1/12A2/12A3/12A4, 12B1/12B2/12B3/12B4 and 12C1/12C2/13C3/12D4). Aesthetic Objective (ODWO = 5 mg/L)

Elevated DOC in bedrock (Figures 12A1 through 12A4), and deeper silty clay (Figures 12B1 through 12B4) are expected as a background condition within the lower units. As shown on Figure 12A1 and 12A2, the highest concentrations of DOC in bedrock are located in the east of the Expansion Area. The elevated DOC in the extreme southwest of the EOWHF (MW96-6Ar) in the summer and fall 2021 monitoring rounds is considered anomalous. The overlying and the highest concentrations in deeper silty clay and shallow silty clay (Figures 12B4, 12C4) are east and south of the EOWHF.

4.6 SITE PLANS AND CROSS-SECTIONS OF HYDROGEOLOGICAL CONDITIONS

The current land conditions for the On-Site Study Area are depicted on Figure 2.

Hydrostratigraphic cross sections were prepared, with alignments shown on Figure 13. The sections include two west-east orientations as Figures 14 and 15 and six south-north orientations as Figures 16 to 21.

A discussion of stratigraphy, including aspects of thickness, depth, character and geometry is presented in Section 5.1.

4.7 HYDRAULIC CONDUCTIVITY

The hydraulic conductivity tests conducted in the Expansion Area and interpreted values are summarized in Table 4. The hydraulic conductivity are presented for the shallow and deep silty clay, the till and the bedrock. Ranges are also provided for the EOWHF Area, for each layer (Tetra Tech, 2018).

The hydraulic conductivity for the glaciomarine deposit (silty clay) was assessed using diverse methods. Below are the applied methods and interpreted values.

- By one-dimensional consolidation method. This test assesses relatively undisturbed soil. Range from 4.7×10^{-11} m/s to 1.3×10^{-10} m/s.
- By the laboratory permeameter method. This test assesses the vertical hydraulic conductivity of re-worked soils. In the Expansion Area, the range was from 1.4×10^{-9} to 4.1×10^{-9} m/s for the Expansion Area. For the EOWHF Area, values for the shallow clay and deeper clay were 3×10^{-6} and 4×10^{-10} m/s, respectively.
- By the bail test method, for “S” series wells in shallower weathered silty clay (less than 4.5 mbg). In the Expansion Area, the range was from 6.6×10^{-9} to 5.0×10^{-6} m/s. This test assesses the horizontal hydraulic conductivity of in-situ weathered clay. For the EOWHF Area, no similar tests were performed.
- By the bail test method, for “C” series wells in deeper silty clay (screen depths greater than 5.0 mbg). This test assesses horizontal hydraulic conductivity of in-situ unweathered clay. In the Expansion Area, the range was from 1.8×10^{-9} to 3.4×10^{-8} m/s. The higher part of the range reflects the earlier steeper portion of the recovery curve in monitoring wells MW20-8C and MW20-11C. However, the curves after about four hours indicate values closer to the 10^{-9} m/s range that dominate at a larger scale. These latter values are similar to values observed in monitoring wells MW20-4C and MW20-7C. For the EOWHF Area, no similar tests were performed.

The hydraulic conductivity for the gravelly sand till was estimated using two methods. Below are the applied methods and interpreted values.

- By bail test method. This test assesses horizontal hydraulic conductivity of in-situ till. For the Expansion Area, the range was from 5.9×10^{-7} to 7.9×10^{-6} m/s. For the EOWHF Area,

the range was from 1.7 x 10^{-7} to 8.4 x 10^{-6} m/s, which is similar to the Expansion Area.

- By Hazen formula. This test assesses hydraulic conductivity using the finer soil fraction. Range from 1.5 x 10^{-7} to 3.3 x 10^{-6} m/s. The d_{10} values ranged from 0.0039 to 0.0182 mm.

The hydraulic conductivity for the bedrock was estimated using one method. Below are the applied methods and interpreted values.

- By the bail test method. This test assesses horizontal hydraulic conductivity of adjacent in-situ bedrock. Responsive wells indicate the bulk permeability due to adjacent fractures. In the Expansion Area, for "D" series wells that recovered, values ranged from 7.3 x 10^{-6} to 1.4 x 10^{-5} m/s. However, the following wells were non-responsive: MW20-1D, MW20-11D, MW20-9D, MW20-18D. Non-responsive wells reflect rock with no conductive fractures within proximity. In the EOWHF Area, the range was 1.7 x 10^{-7} to 3.1 x 10^{-5} m/s, which is relatively similar.

Different tests conducted on the same unit may produce a different range of values due to assessing different volumes of soil material, with larger volumes having a greater potential to include soil or bedrock fractures, fine sand seams, or other heterogeneities. The laboratory permeameter method measures vertical hydraulic conductivity whereas a bail / slug test measures horizontal hydraulic conductivity.

Overall for the Expansion Area, the silty clay layer appears to be approximately 100 to 1000 times lower hydraulic conductivity compared to the gravelly sand till layer. The upper 3 m of bedrock is approximately 10 times more conductive compared to the gravelly sand till layer. The hydraulic conductivity of the shallow weathered silty clay compared to the deeper unweathered silty clay is variable. As examples, at MW20-8 the shallower zone of silty clay is 9 times more conductive where at MW20-11 the deeper zone of silty clay is 5 times more conductive.

4.8 WATER BALANCE

Monthly and annual precipitation and temperature data are discussed in Section 2.10. The monthly data were used to estimate the monthly evapotranspiration amount using the method of Thornthwaite and Mather. The resulting long-term average annual evapotranspiration amount is estimated to 582 mm/year, based on the sum of monthly estimates, as presented on Table 7.

The moisture surplus on a monthly basis is estimated by subtracting the evapotranspiration amount from the precipitation amount. The moisture surplus amount is zero when the monthly average temperature falls below the freezing point. The long-term annual moisture surplus is the sum of monthly values, which is estimated to be 473 mm/year.

Moisture surplus is apportioned to become either runoff or infiltration that replenishes the groundwater regime. Using the MECP (1995) method, approximately 50% of the 473 mm/year moisture surplus is infiltrated under current conditions, which is 237 mm/year. This is based on an infiltration factor of 0.50, that is the sum of subfactors of slope at 0.25 for flat land, soil at 0.15 for impervious clay and vegetation at 0.10 for the cultivated condition.

The infiltration values calculated are interpreted to represent an estimate of long-term average conditions using a simplified approach. It must be noted that infiltration processes actually have many complex contributing factors, including soil texture, vertical hydraulic gradient direction, vegetation growth density, rain event duration, antecedent wetting history, snow pack, ground freezing and wind speed, to name a few. There is significant annual variation in meteorological factors.

4.9 CONTAMINANT ATTENUATION CAPABILITIES IN THE EVENT OF LEACHATE RELEASE

The undisturbed silty clay has a vertical hydraulic conductivity range of 4.7×10^{-11} m/s to 1.3×10^{-10} m/s, as indicated by the one-dimensional consolidation method. Thus, the clay should function to attenuate the migration of leachate to groundwater.

We recommend that the landfill designers consider the conditions in the southeast corner of the expansion area in developing the design of the leachate containment system (e.g. reduced thickness of the silty clay layer relative to other parts of the site). The silty clay layer base rises to higher elevation (shallower depth) in the eastern portion of the Expansion Area, as mapped on Figure 22.

5.0 SUMMARY OF EXISTING CONDITIONS

5.1 GEOLOGICAL AND HYDROGEOLOGICAL CONDITIONS

The EOWHF Area and the Expansion Area are essentially underlain by a substantially thick package of overburden layers that rests upon bedrock. The stratigraphy, as described below was observed at boreholes in the Expansion Area, in increasing depth from grade. The summarized stratigraphy was consistent across the site, with minor exceptions.

- Topsoil / peat. Comprised of a substantial organic component with wood chips and rootlets. Thickness ranges from 0.3 to 2.1 m, with an average of 1.3 m. The topsoil/peat was absent at two locations. Regional mapping (OGS, 2010) indicates peat, muck and marl.

- Silty clay. Texture is dominantly clay with a minor component that is either silty or with some silt, sometimes with trace sand. The depth to this layer's base ranges from 4.7 to 17.8 mbg, with an average depth of 11.8 mbg. The elevation of the base ranges from 48.7 to 62.5 masl, with an average of 54.8 masl, as shown on Figure 21. This layer is interpreted to be the Champlain Sea glaciomarine deposit. The silty clay layer rests upon the till, except at MW20-8 along the eastern side where the till is absent. Grain size analysis indicates the following ranges: Gravel = 0 to 2%, average 0.3%; Sand = 1 to 8%, average 2.3%; Silt = 11 to 42%, average of 22.5%; clay = 51 to 87%, average of 74.8%.

- Sandy gravel till. Texture is dominantly sandy gravel with some silt. At MW20-5 the texture is silty sandy gravel. The depth to the layer's base ranges from 4.9 to 23.7 mbg, with an average of 12.0 mbg. The thickness of the layer ranges from 0.6 to 10.6 m, with an average of 2.5 m. The till layer is absent at MW20-8 in the east. It is thin (<1.0 m) along the southern and eastern boundaries (MW20-4, MW20-6, MW20-10, and MW20-13) with the exception of MW20-18 where it thickens to 4.4 m.

- Bedrock. The lithology is dominantly limestone, sometimes with shale interbeds. The top of bedrock occurs at depths ranging from 5.7 to 23.7 mbg, with an average depth of 14.4 mbg. The top of bedrock surface elevation is variable, ranging from 44.0 to 61.5 masl, with an average of 52.2 masl, as shown on Figure 23.

The hydrogeological conditions include the water table, hydraulic gradients and hydraulic conductivity.

- Water table. The water table surface elevation declines northward, from approximately 67.0 masl near to Lafleche Road to approximately 64.0 masl near to the intersection of Concession Road 7 / Road 700 and Highway 138. The depth to water table on April 8, 2020 ranged from 0.5 to 1.5 mbg, with an average of 0.9 mbg. The water table in the summer of 2021 ranged from 0.7 to 1.8 mbg. See Figures 7C1/7C2/7C3/7C4 for elevations.

- Gradients. The water table elevations indicate a horizontal hydraulic gradient with shallow groundwater generally moving northward. Similarly, the piezometric elevations in till and in bedrock indicate that a horizontal hydraulic gradient with generally northward movement.

The vertical hydraulic gradient is variable between stratigraphic layers. Refer to Figures 7A1 through 7C4 for maps of piezometric elevations in the till and bedrock.

- Hydraulic conductivity. The silty clay layer ranged from 5×10^{-11} to 5.0×10^{-6} m/s, with values generally below 1×10^{-8} m/s. The sandy gravel till layer ranged from 1.5×10^{-7} to 3.3×10^{-6} m/s. The bedrock ranged from 7.3×10^{-6} to 1.4×10^{-5} m/s, where not fractured. In general, the upper bedrock in the Expansion Area appears to be approximately 10 times more permeable than the overlying sandy gravel till and the silty clay is less permeable than the sandy gravel till, possibly by factors of 10 to 1,000. The hydraulic conductivity range for the gravelly sand overlapped the hydraulic conductivity range for the bedrock, indicating there may be some locations where the sandy gravel till and bedrock exhibit similar hydraulic conductivity values.

Groundwater in limestone with shale and in Champlain Sea sediments is noted for often being highly mineralized. The EOWHF Area, Expansion Area and Study Areas are all located within Champlain Sea sediments underlain by limestone, with shale in places. As a result, mineralized background groundwater conditions are expected below the Expansion Area and EOWHF Area. Groundwater quality for the Expansion Area and EOWHF Area are summarized as follows:

- Eastern Expansion Area: Elevated hardness, dissolved organic carbon (DOC) and total dissolved solids (TDS) are expected as background conditions in bedrock. Elevated TDS in deeper silty clay is independent of landfill impacts. Elevated chloride in bedrock is localized, and likely results from the historic depositional environment.

- EOWHF Area: Elevated alkalinity was observed in the deeper silty clay below the northeastern section of the EOWHF Area (MW96-3B). Elevated hardness in deeper silty clay and shallow clay were present. It was concluded that these do not appear to be related to leachate impacts.

  There are no chloride impacts evident in silty clay/clay below the EOWHF Area. Elevated chloride in bedrock is localized, and likely results from the historic depositional environment.

  Elevated DOC in bedrock is expected as a background condition in bedrock. The DOC concentration of 89 mg/L detected in Summer 2021 and 110 mg/L in Fall 2021 (MW96-6Ar; refer to Figures 12A3 and 12A4) are considered anomalous. Corresponding DOC concentrations in the Fall of 2020 and Spring of 2021 were both 5 mg/L. DOC concentrations in the overlying silty clay are all below 10 mg/L over the Fall 2020 to Fall 2021 monitoring rounds.

5.2 LANDFILL DESIGN PARAMETERS

For the Expansion Area, laboratory permeameter tests, utilizing re-worked samples of native silty clay indicate hydraulic conductivity values that range from 1.4×10^{-9} to 4.1×10^{-9} m/s. The vertical hydraulic conductivity values of undisturbed silty clay samples range from 4.7×10^{-11} m/s to 1.3×10^{-10} m/s.

The till layer and bedrock layer below the native silty clay are too permeable to function as an attenuation layer. The till layer and bedrock are aquifers that are used by private supply wells in the Off-Site Study Area and beyond. Where practical, a suitable thickness of undisturbed silty clay should remain in place.

Given the low hydraulic conductivity of the native silty clay, and the performance of the existing EOWHF in the same hydrogeological regime, the Expansion Area is suitable for the proposed landfill development.

6.0 CLOSURE

This hydrogeological review was prepared in accordance with the terms of reference for this project as agreed upon by GFL Environmental Inc. and generally accepted engineering or environmental consulting practices in this area. The reported information is believed to provide a reasonable representation of the general environmental conditions at the site, however, the data were collected at specific locations and conditions may vary at other locations and over time.

This report has been prepared for the sole uses of GFL Environmental Inc. Terrapex Environmental Ltd. accepts no liability for claims arising from the use of this report, or from actions taken or decisions made as a result of this report, by parties other than GFL Environmental Inc.

Respectfully submitted,
TERRAPEX ENVIRONMENTAL LTD.

MW104 - MONITORING WELL DESIGNATION

STATIC WATER LEVEL-

DEPTH OF SOIL INTERFACE(m bg)- 3.7-

- SCREENED ZONE

- BOREHOLE

NOTES:
1. Soil and groundwater only known at borehole locations.
2. Upper 0.6 m +/- was frozen at time of drilling
3. Groundwater levels measured on 8 April 2020 for MW20-# and on 7 May 2020 for MW96-#.
4. Monitoring wells are actually in clusters with separate boreholes. Shown here in same pipe for clarity.

[1] Standards from Soil, Ground Water and Sediment Standards for Use Under Part XV.1 of the Environmental Protection Act (April 15, 2011 and as amended)
Table 2: Full Depth Generic SCS in a Potable Ground Water Condition
All Types of Property-Use, Fine- to Medium-Textured Soil

[2] Standards from O.Reg. 169/03: Ontario Drinking Water Quality Standards for Use Under the Safe Drinking Water Act (2002 and as amended)
Schedule 2: Chemical Standards

[3] Aesthetic Objectives and/or Operational Guidelines from O.Reg. 169/03: Ontario Drinking Water Quality Standards for Use Under the Safe Drinking Water Act (2002 and as amended)

AO	Aesthetic Objective
OG	Operational Guideline
-	No standard, not applicable, not analyzed
m bg	meters below grade
RPD	Relative percent difference
Value	Exceeds Table 2 standard
Value	Exceeds ODWQS standard or ODWO objective
Value	Exeeds ODWQS and Table 2
Value	Detection limit exceeds standard

[1] Standards from Soil, Ground Water and Sediment Standards for Use Under Part XV.1 of the Environmental Protection Act (April 15, 2011 and as amended)
Table 2: Full Depth Generic SCS in a Potable Ground Water Condition
All Types of Property-Use, Fine- to Medium-Textured Soil

[2] Standards from O.Reg. 169/03: Ontario Drinking Water Quality Standards for Use Under the Safe Drinking Water Act (2002 and as amended)
Schedule 2: Chemical Standards

[3] Aesthetic Objectives and/or Operational Guidelines from O.Reg. 169/03: Ontario Drinking Water Quality Standards for Use Under the Safe Drinking Water Act (2002 and as amended)

AO Aesthetic Objective
OG Operational Guideline
- No standard, not applicable, not analyzed
m bg meters below grade
RPD Relative percent difference
Value Exceeds Table 2 standard
Value Exceeds ODWQS standard or ODWO objective
Value Exeeds ODWQS and Table 2
Value Detection limit exceeds standard

1 Standards from Soil, Ground Water and Sediment Standards for Use Under Part XV.1 of the Environmental Protection Act (April 15, 2011 and as amended), Table 2: Full depth Generic SCS in a Potable Ground Water Condition, All Types of Property-Use, Fine- to Medium-Textured Soil

2 Standards from O.Reg. 169/03: Ontario Drinking Water Quality Standards for Use Under the Safe Drinking Water Act (2002 and as amended), Schedule 2: Chemical Standards

3 Aesthetic objectives (AO) and operational guidelines (OG) from: Ontario Drinking Water Standards, Objectives and Guidelines, June 2003 (Revised June 2006)

- No standard, not applicable, not analyzed

m bg meters below grade

Value Exceeds Table 2 standard

Value Exceeds ODWQS or ODWO

Table 4 – Summary of Hydraulic Conductivity Test Results

One-Dimensional Consolidation Test Results

Borehole No.	Sample Depth (mbgs) and No.		Coefficient of Permeability (m/sec)
MW20-2D	5.0; Sample 5	Clay	4.8×10^{-11}
MW20-3D	6.1; Sample 7	Silty Clay	1.3×10^{-10}
MW20-8D	3.0; Sample 4	Silty Clay	5.1×10^{-11}
MW20-9D	8.0; Between Samples 6 and 7	Silty Clay	9.5×10^{-11}
MW20-10D	9.8; Sample 7	Silty Clay	1.0×10^{-10}
MW20-11D	11.0; Sample 7	Silty Clay	4.7×10^{-10}

Compaction Permeameter Test Results

Borehole No.	Sample No.	Sample Description	Hydraulic Conductivity (m/s)
MW20-1D	5	Silty Clay	2.5×10^{-9}
MW20-4D	7	Silty Clay	1.5×10^{-9}
MW20-5D	4B	Silty Clay	2.5×10^{-9}
MW20-6D	4	Silt and Clay	1.4×10^{-9}
MW20-9D	4	Silty Clay	4.1×10^{-7}

Grain-size Analyses - Till (Hazen)

Borehole No.	Sample Depth (mbgs) and No.	Sample Description	D_{10} (mm)	Hydraulic Conductivity (m/s)
MW20-3D	10.4; Sample 12	TILL: SANDY GRAVEL, some silt, trace clay	0.0182	3.3×10^{-6}
MW20-5D	8.1; Sample 5B	TILL: SILTY SANDY GRAVEL, trace clay	0.0039	1.5×10^{-7}
MW20-5D	10.3; Sample 7	TILL: SANDY SILTY GRAVEL, trace clay	0.0048	2.3×10^{-7}
MW20-9D	14.2; Sample 10	TILL: GRAVELLY SILTY SAND, trace clay	0.0115	1.3×10^{-6}

Single-Well Response Test Results

Borehole No.	Sample Description	Hydraulic Conductivity (m/s)
MW20-12S	Shallow Clay	4.7×10^{-8}
MW20-11S	Shallow Clay	6.6×10^{-9}
MW20-11C	Clay	3.4×10^{-8}
MW20-10D	Bedrock	1.2×10^{-5}
MW20-8S	Shallow Clay	2.9×10^{-7}
MW20-8C	Clay	3.4×10^{-8}
MW20-7C	Clay	1.8×10^{-9}
MW20-6S	Shallow Clay	5.1×10^{-6}
MW20-6D	Bedrock	1.3×10^{-5}
MW20-5T	Till	7.9×10^{-6}
MW20-4D	Bedrock	1.3×10^{-5}
MW20-4C	Clay	9.2×10^{-9}
MW20-3D	Bedrock	7.9×10^{-6}
MW20-1T	Till	1.3×10^{-6}

Notes

Elevations measured by Topcon GNSS device, to centimetre accuracy

m asl = metres above sea level

m bmp = metres below measurement point (top of pipe)

m bg = metres below ground

Monitoring wells were purged dry for development between February 25 and March 3, 2020

May monitoring event for 96 series wells on May 7, 2020 was completed by others

Notes

MW20-series well elevations measured by Topcon GNSS device, to centimetre accuracy

Elevations from other locations obtained from previous reports

Groundwater monitoring was conducted by others

m asl = metres above sea level

m bmp = metres below measurement point (top of pipe)

m bg = metres below ground

Table 7
Moisture Surplus and Unit Infiltration Rate
Lafleche Expansion, Moose Creek

	Units	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual

Evaporation per day	(mm/day)	0	0	0	1.035	2.585	3.915	4.331	3.745	2.495	1.134	0.174	0.000	
Infiltration Rate (factor = 0.50)	(mm)	41.9	29.9	34.6	26.0	6.7	-8.2	-15.2	-8.2	14.2	30.1	45.1	39.6	237

Notes.
1. Moisture surplus calculations based on Thornthwaite method
2. Values are approximate. Numerous site specific and meteorological factors can modify values.
3. Infiltration calculations based on Government of Ontario (2003) method.
4. Infiltration factor sum of slope of 1.7 m/1000 m (subfactor=0.25), clayey silt (subfactor=0.15), cultivate ground cover (subfactor=0.10).
5. Data based on St. Albert climate station, normals from 1981-2010.

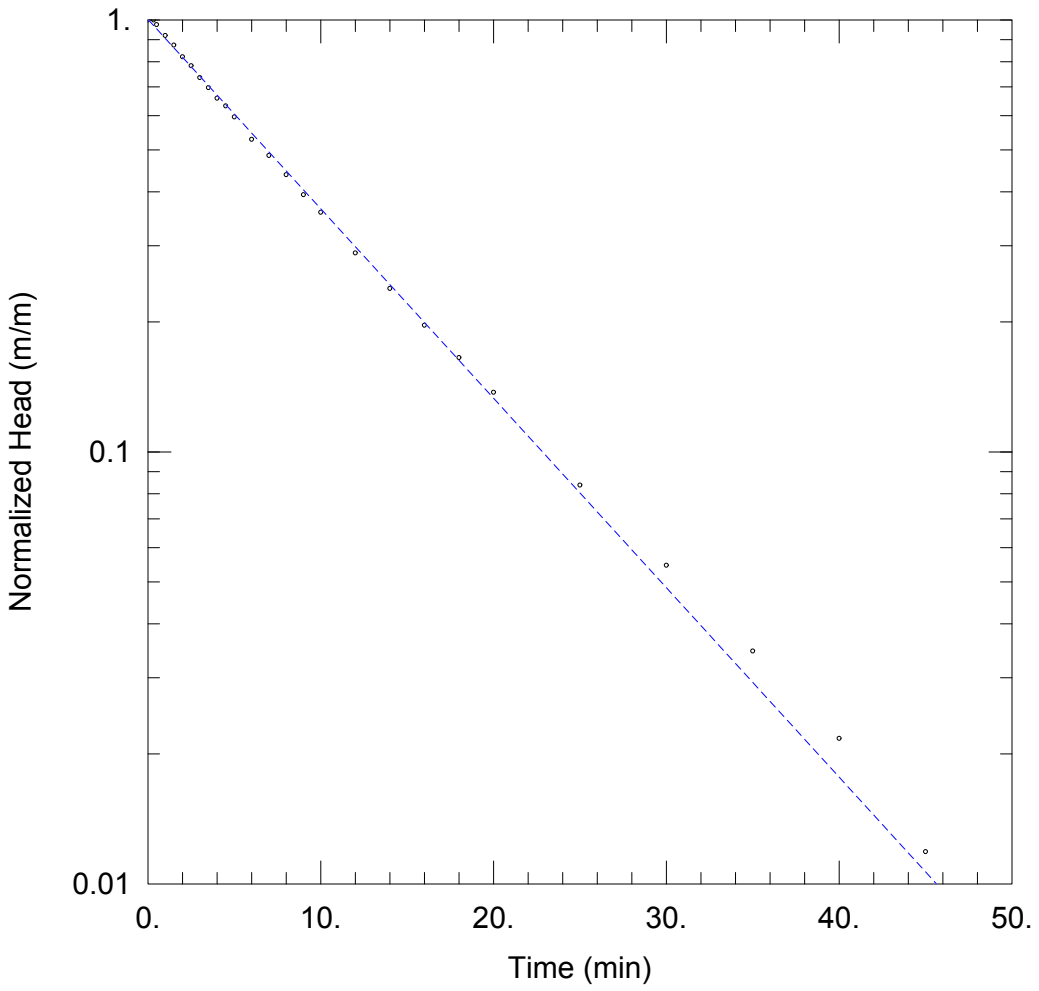
APPENDIX VI

HYDRAULIC CONDUCTIVITY TESTING



HYDROGEOLOGICAL REVIEW

Data Set: H:\...\MW20-1T.aqt
Date: 04/22/20 Time: 17:38:48

PROJECT INFORMATION

Company: Terrapex Environmental Ltd.
Client: GFL
Project: CO749.00
Location: Concession 10, Moose Creek, ON
Test Well: MW20-1T
Test Date: March 26, 2020

AQUIFER DATA

Saturated Thickness: 15.8 m Anisotropy Ratio (Kz/Kr): 0.1

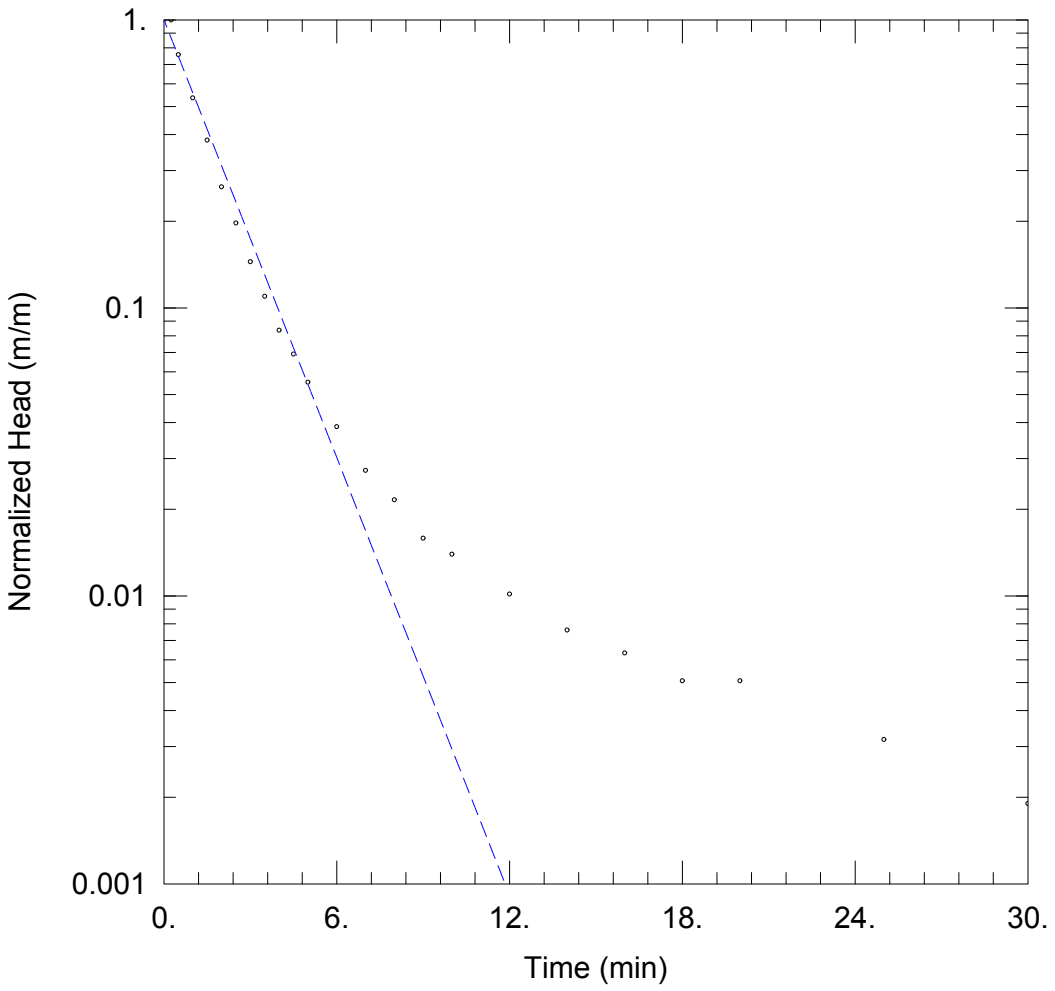
WELL DATA (MW20-1T)

Initial Displacement: 2.947 m
Total Well Penetration Depth: 13.79 m
Casing Radius: 0.0254 m
Static Water Column Height: 13.8 m
Screen Length: 1.52 m
Well Radius: 0.1 m

SOLUTION

Aquifer Model: Unconfined
Solution Method: Bouwer-Rice

K = 1.25E-6 m/sec
y0 = 2.955 m



HYDROGEOLOGICAL REVIEW

Data Set: H:\...\MW20-3D.aqt
Date: 04/22/20 Time: 17:39:25

PROJECT INFORMATION

Company: Terrapex Environmental Ltd.
Client: GFL
Project: CO749.00
Location: Concession 10, Moose Creek, ON
Test Well: MW20-3D
Test Date: March 27, 2020

AQUIFER DATA

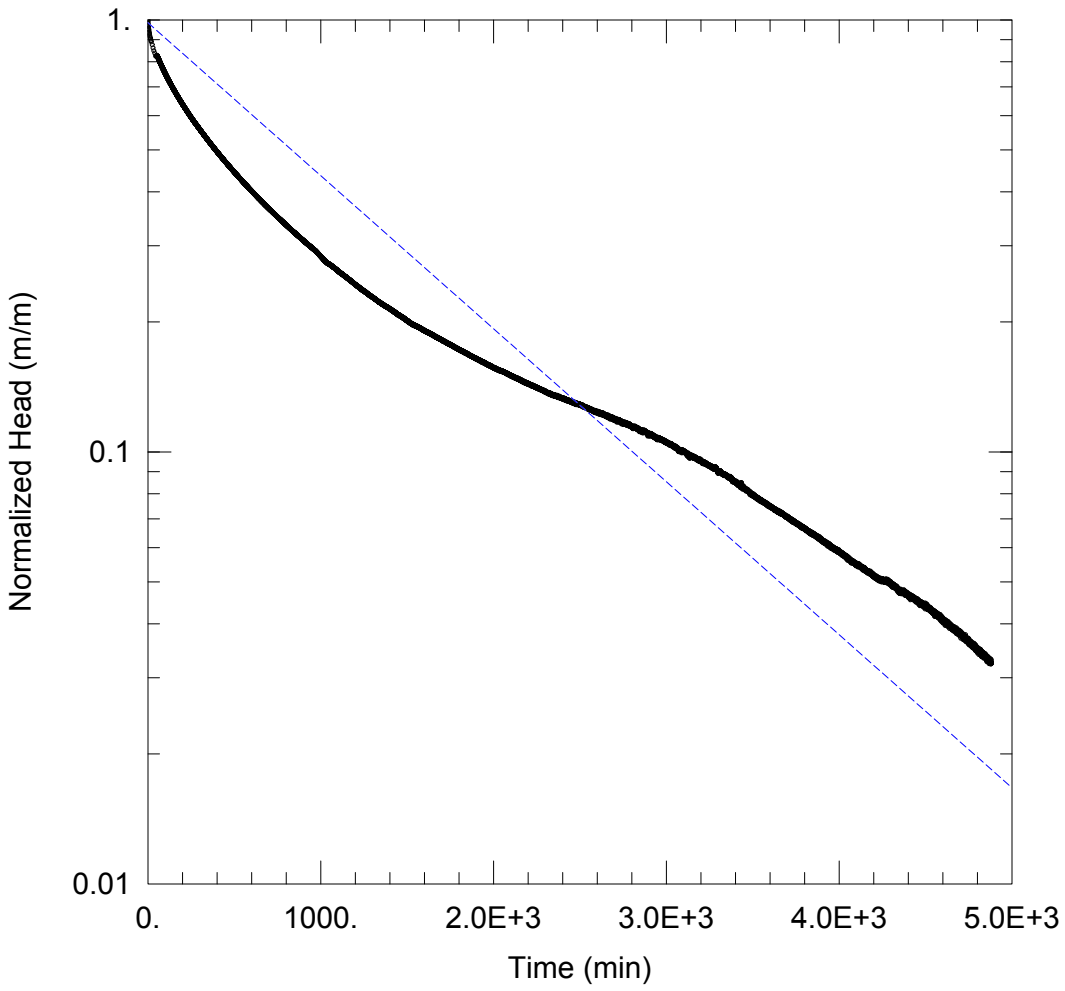
Saturated Thickness: 17.6 m Anisotropy Ratio (Kz/Kr): 0.1

WELL DATA (MW20-3D)

Initial Displacement: 1.577 m
Total Well Penetration Depth: 15.61 m
Casing Radius: 0.0254 m
Static Water Column Height: 15.6 m
Screen Length: 1.52 m
Well Radius: 0.1 m

SOLUTION

Aquifer Model: Unconfined
Solution Method: Bouwer-Rice
K = 7.316E-6 m/sec
y0 = 1.577 m



HYDROGEOLOGICAL REVIEW

Data Set: H:\...\MW20-4C.aqt

Company: Terrapex Environmental Ltd.
Client: GFL
Project: CO749.00
Location: Concession 10, Moose Creek, ON
Test Well: MW20-12S
Test Date: March 31, 2020

AQUIFER DATA

Saturated Thickness: 5.8 m Anisotropy Ratio (Kz/Kr): 0.1

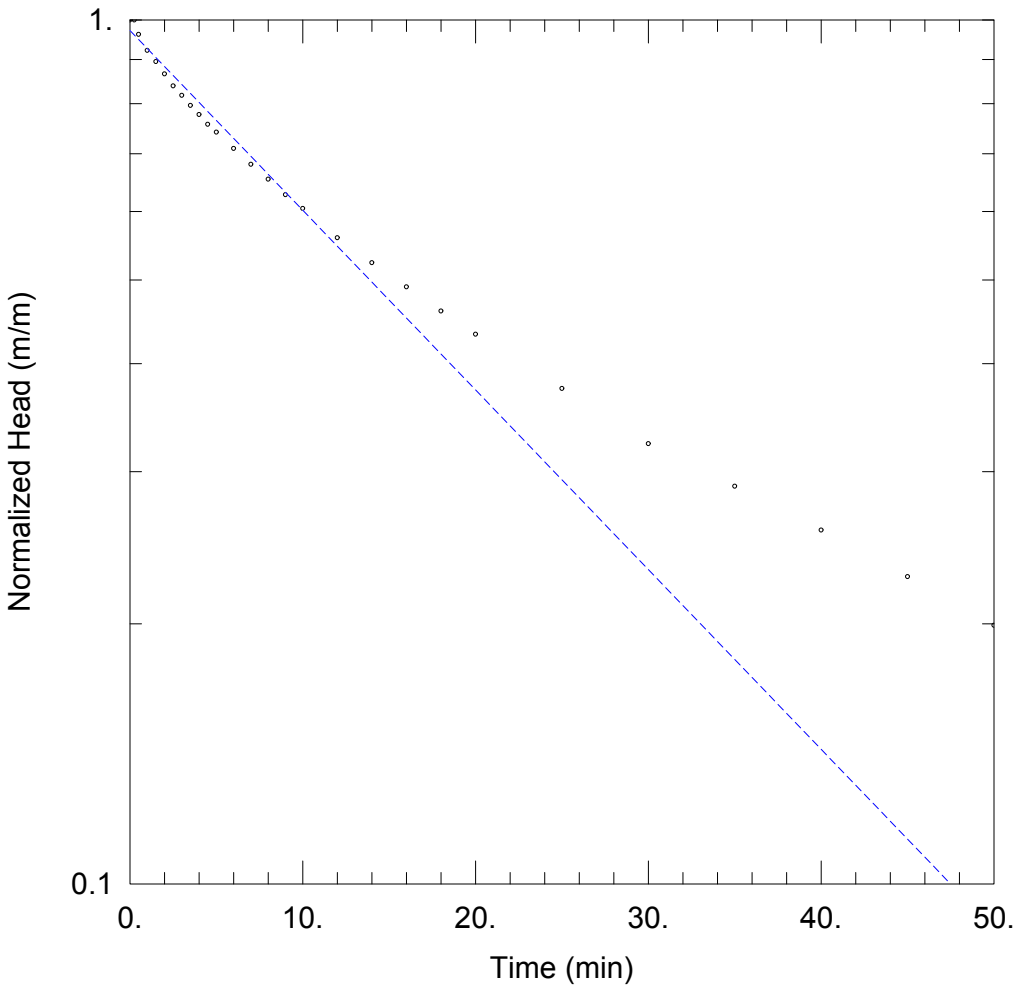
WELL DATA (MW20-12S)

Initial Displacement: 2.013 m
Total Well Penetration Depth: 3.8 m
Casing Radius: 0.0254 m
Static Water Column Height: 3.8 m
Screen Length: 1.52 m
Well Radius: 0.1 m

SOLUTION

Aquifer Model: Unconfined Solution Method: Bouwer-Rice

K = 4.047E-8 m/sec y0 = 1.541 m



HYDROGEOLOGICAL REVIEW

Data Set: H:\...\MW20-15T.aqt
Date: 04/22/20 Time: 17:45:59

PROJECT INFORMATION

Company: Terrapex Environmental Ltd.
Client: GFL
Project: CO749.00
Location: Concession 10, Moose Creek, ON
Test Well: MW20-15T
Test Date: March 27, 2020

AQUIFER DATA

Saturated Thickness: 14.9 m Anisotropy Ratio (Kz/Kr): 0.1

WELL DATA (MW20-15T)

Initial Displacement: 2.831 m
Total Well Penetration Depth: 12.89 m
Casing Radius: 0.0254 m
Static Water Column Height: 12.9 m
Screen Length: 1.52 m
Well Radius: 0.1 m

SOLUTION

Aquifer Model: Unconfined Solution Method: Bouwer-Rice

K = 5.888E-7 m/sec y0 = 2.752 m
