

Appendix P – Groundwater Impact Assessment

- P.1 Leachate Data
- P.2 Permitted AGQS Values
- P.3 Model Input Documentation
- P.4 Baseline Model
- P.5 Sensitivity Analyses

P.1 – Leachate Data

Well Name	Parameter Name	Sample Date	Units	Result	Qualifier	SQL
L302	1,1,1,2-Tetrachloroethane	05/17/10	ug/L	30	U	30

P.3 – Model Input Documentation

Thickness of Wadsworth Formation/Till below Excavation Grades

LEGEND

- APPROXIMATE PROPOSED FACILITY BOUNDARY
- APPROXIMATE PROPOSED EXPANSION WASTE BOUNDARY
- 30 INTERPOLATED THICKNESS CONTOUR

NOTES

1. EXISTING CONTOURS DEVELOPED FROM SITE AERIAL TOPOGRAPHIC SURVEY BY CQM ON 10/22/2018.
2. FOR CLARITY, NOT ALL SITE FEATURES MAY BE SHOWN.
3. CURRENT TOPOGRAPHY MAY DIFFER FROM THAT SHOWN.
4. THICKNESS OF WADSWORTH TILL BELOW EXCAVATION GRADES DEVELOPED FROM COMPARING THE DESIGN BOTTOM OF LINER/EXCAVATION AND THE TOP ELEVATION OF SHALLOW DRIFT SURFACE.
5. THICKNESS OF WADSWORTH TILL UNDER LINER FLOOR (EXCLUDES SIDESLOPES)
 MINIMUM THICKNESS = 19.7'
 MAXIMUM THICKNESS = 43.6'
 AVERAGE THICKNESS = 33.7'

Problem Statement

Calculate outward leakage through the composite liner design based on Giroud et al. (1989).

Given

- 1 Outward gradient with 1 foot of differential head acting on the liner during operational and post-closure periods.
- 2 Poor contact between the geomembrane and the compacted soil liner (CSL) is conservatively assumed.
- 3 Illinois Environmental Protection Agency (IEPA) accepted geomembrane defect area of 4 cm² per acre.

Solution

The volumetric rate of leakage through geomembrane defect (Q) expressed in m³/s/acre =

$$Q = 1.15 hw^{0.9} a^{0.1} ks^{0.74} \quad \text{Giroud et al. (1989)}$$

Where,

hw = Differential head acting on top of the composite liner

a = Area of the geomembrane defect

ks = Saturated hydraulic conductivity of the CSL

Q = Volumetric rate of leakage = $1.15 hw^{0.9} a^{0.1} ks^{0.74}$

q_v = Vertical leakage rate in m/s = (Q/1 acre/4047 m²)

- 1) 1 foot of differential head on CSL (1 E-07 cm/s).

hw = Differential head acting on the composite liner = 1.0 ft = 0.3048 m

a = Area of the geomembrane defect = 4.00 cm²/acre = 0.0004 m²/acre

ks = Saturated hydraulic conductivity of the CSL = 1E-07 cm/s = 1E-09 m/s

Q = Volumetric rate of leakage = $1.15 hw^{0.9} a^{0.1} ks^{0.74}$ = 3.95E-08 m³/s/acre

q_v = Vertical leakage rate in m/s = (Q/1 acre/4047 m²) = 9.76E-12 m/s = **3.08E-04 m/y**

variation in concentration with depth in the soil at the end of each test. The consistency of results demonstrates the power of the analytical model (program POLLUTE) and provides some con-

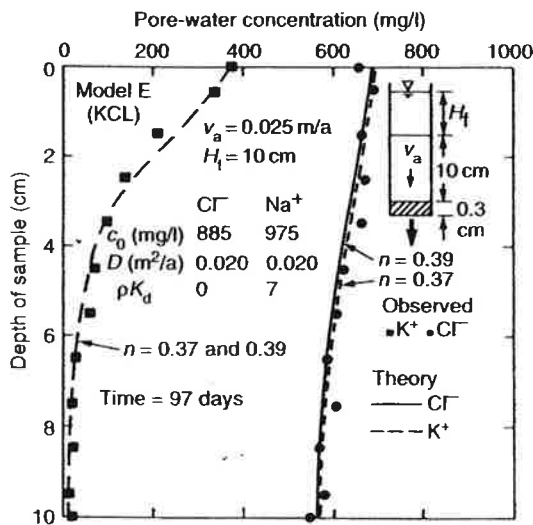

Figure 8.11 Chloride and potassium concentration versus depth in sample for model E (modified from Rowe *et al.*, 1988).

fidence in the parameters D and ρK_d for the clay and source fluids examined.

To provide an indication of parameter variation that might be expected for a given soil, a number of tests were duplicated. The diffusion coefficient, D , for chloride was deduced for each model and ranged between 0.018 and 0.02 m²/a with an average value of 0.019 m²/a. This small variation in D does not appear to be related to small differences in Darcy velocity, nor does it appear to be particularly related to the nature of the associated cation (see Table 8.3). Rather, the variability from 0.018 to 0.02 m²/a is seen as an indication of the level of repeatability that may be achieved for this type of test.

* 0.019 m²/a

The application of an effective stress to the soil sample adopted in these tests is not an essential part of the proposed technique for determining the parameters D and K_d . Tests performed for the particular combination of clay and permeants considered herein gave similar results both with and without the application of the effective stress. However, for some combinations of clay and permeant, shrinkage of the clay may occur in the absence of a confining stress and this can give quite misleading results (e.g., see Quigley and Fernandez, 1989). For these clays, and for GCLs (see Chapter 12), tests should be performed at an effective stress similar to that anticipated in the field.

8.3.2 Pure diffusion tests

In many cases, it is not necessary to perform an advection-diffusion test. Under these circumstances, a simple diffusion test can be performed for boundary conditions shown in Figure 8.2. In this test, the soil sample is placed in a Plexiglass cylinder by trimming the sample to a size marginally greater than the specimen and then pressing the specimen into the cylinder, using a cutting shoe attached to the cylinder, to perform the final trim. This procedure is found to work well for many clays. However, it does not work well for clays with a significant stone content because the

uide

Sublayers

The number of sublayers in each layer is primarily used in the output of the calculated concentrations with depth; a concentration will be calculated at each sublayer interface.

The maximum thickness of each sublayer is 5 units. The number of sublayers is automatically increased if required to keep their thickness to less than 5. For example, if the layer thickness was 50 m and it had 5 sublayers (giving a sublayer thickness of 10), the program will automatically adjust the number of sublayers to 10.

If the time-varying properties is selected, the accuracy of the results will depend on the number of sublayers.

Thickness

The thickness of the layer must be specified, this is the total thickness of all the sublayers in the layer.

Dry Density

The dry density of the layer, expressed in consistent units with those used throughout the model.

Porosity

This is the porosity of the layer, which must be greater than 0 and less than or equal to 1. If the layer is being used to represent a geomembrane the porosity should be set to 1.

Horizontal & Vertical Diffusion/Dispersion Coefficients

These are the horizontal and vertical coefficients of hydrodynamic dispersion for the layer:

$$D_{xx} = D_{ex} + D_{mex}$$
$$D_{zz} = D_{ez} + D_{mez}$$

where,

D_{ex} and D_{ez} = diffusion coefficients for the species,
 D_{mex} and D_{mez} = coefficients of mechanical dispersion.

For intact clayey layers, diffusion will usually be the controlling factor and dispersion will often be negligible [Gillham and Cherry, 1982, Rowe, 1987]. In sandy layers, dispersion will tend to be the controlling factor.

Horizontal and Vertical Darcy Velocities

$$V_{hx} = nv_x$$
$$V_{hz} = nv_z$$

where,

n = effective porosity,
 v_x and v_z = seepage or groundwater velocities.

Distribution Coefficient

This is the distribution coefficient for the layer. The sorption-desorption of a non-conservative species of contaminant is assumed to be linear such that:

$$S = K_d * c$$

where,

S = solute sorbed per unit weight of soil,
 K_d = distribution (partitioning) coefficient,
 c = concentration of contaminant.

This is a reasonable approximation for low concentrations of contaminant, however at high concentrations sorption may not be linear and more complex relationships should be used. If there is no sorption (i.e., a conservative species) the distribution coefficient is zero.

Half-Life

If the contaminant species experiences radioactive or biologic decay in a layer, this option can be used to specify the half-life of the species in the layer. First order (exponential) decay is assumed for both radioactive and biological decay, eg.

$$c(t) = c(0) e^{-\lambda t}$$

where,

$c(t)$ = concentration at time t ,
 $c(0)$ = initial concentration,
 λ = decay constant = $0.693147/\text{half-life}$,

If there is no decay of the species in the layer, the half-life should be specified as zero which is the same as an infinite half-life ($\lambda = 0$).

read directly off the various density hydraulic conductivity graphs (see Figure 5-36). The uniformity coefficient (C_u) is defined as the ratio of the D_{60} size of the soil (the size than which 60% of the soil is finer) to the D_{10} .

The above can be used where appropriate, to support field tests of hydraulic conductivity. Building an adequate data base of both field and laboratory hydraulic conductivity tests then provides the basis for definition of vertical and horizontal components of hydraulic conductivity in later flow net constructions.

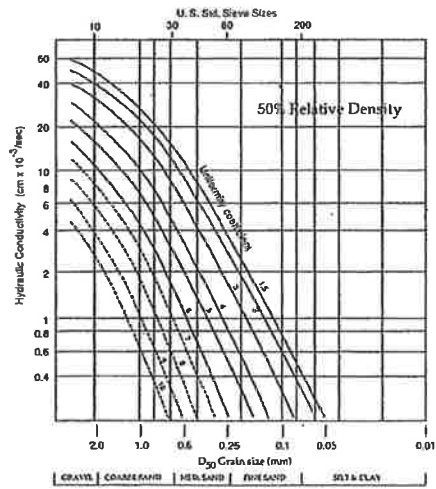

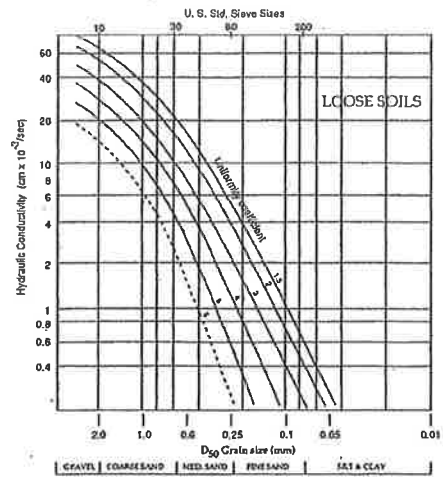

5.6.7 Laboratory Tests For Effective Porosity

An important aquifer characteristic of geologic environments used in time of travel calculations, is effective porosity. Fetter (1980) defines effective porosity as follows: "The amount of interconnected pore space through which fluids can pass, expressed as a percent of bulk volume. Part of the total porosity will be occupied by static fluid being held to the mineral surface by surface tension, so effective porosity will be less than total porosity." The relative value of effective porosity for fine grained sediments such as clays has been the point of significant disagreements between regulatory agencies and

Figure 5-36 Powers Curves for Density and K

the regulated community for a number of years since effective porosity is used in the following equation of seepage velocity:

$$V = \frac{Ki}{n_e} \quad \text{Equation 5-39}$$

V is the average lineal velocity;
 n_e is the effective porosity.
 i is the gradient, and K is hydraulic conductivity.

There is a current controversy centering around using very low values of n_e for fine grained clay sediments. A U.S. EPA guidance document (EPA 1986) proposed using values of effective porosity on the level of 1% for clays. The basis of this low figure is from specific yield determinations of sediments derived from water supply literature (see Walton 1970, p. 34). However, the Glossary of Geology (1987) defines effective porosity as follows: "The percentage of the total volume of a given mass of soil or rock that consists of interconnected interstices. The use of this term as a syn. of specific yield is to be "discouraged." The definition of effective porosity is recognized as not synonymous with specific yield in the technical literature. This departure of n_e from specific yield is especially important in fine grained sediments, since the value of lineal velocity V is so dependent on effective porosity. For example, using a low effective porosity of 1% (as compared to 30%) for a clay confining unit, will change the calculations of lineal velocity as follows:

Assuming $K = 1 \times 10^{-7}$ cm/sec
 $i = dh/dl = 0.5$
 $n_e = 0.01, 0.30$
 1.57 m/year (at 0.01 n_e)
 0.053 m/year (at 0.30 n_e)

Considering the average facility can have thirty years of active life the difference in the two calculations can represent the difference between breaking through confining units some thirty times faster than with the larger value of n_e . The controversy surrounding n_e is difficult, in some ways to understand on a scientific basis, considering effective porosity can be calculated from breakthrough column tests. The following test is described for quantification of n_e for a series of glacial till (confining unit) samples. This testing was performed to: 1) determine the effective transport porosity; and, 2) to allow evaluation of the effect of leachate on the hydraulic conductivity of these potential clay liner materials. These results can ultimately be used in design of recompacted clay liners for

future hazardous waste disposal cells at a potential site, and can be used to estimate effective porosity of unfractured confining unit materials.

A testing program should include both hydraulic conductivity testing and saline solution breakthrough evaluation of a number of confining unit samples. In addition, one should also conduct several reverse breakthrough tests using fresh water as the permeant.

Breakthrough and Leachate Solutions

The initial stages of laboratory tests for specific porosity, including saturation and hydraulic conductivity determination, should be conducted using actual site water obtained during the site assessment investigation.

An example tracer solution used for the column breakthrough portion of the tests consisted of a lithium chloride salt in water. The concentrations of lithium and chloride in the breakthrough tracer solution for the example below were:

- Lithium: 4,800 mg/l
- Chloride: 25,000 mg/l

Experience with the initial portion of column breakthrough testing shows that one will observe that the chloride ions will pass through soil samples at a much faster rate than the lithium ions. The likely reason is that due to cation exchange effects within the clay particles slowed down the passage of the lithium ions. The variation of the observed chloride concentration with time is considered to be the more accurate indicator of breakthrough time and, hence, pore fluid velocity. Therefore, only chloride ion concentrations is measured for the reverse breakthrough tests to maintain a conservative approach to the testing program.

The tracer solution is placed into a tri-axial cell upgradient accumulator (see Figure 5-33) and the concentration of lithium and chloride is then measured in the fluid that permeates out of the sample and is collected in the downgradient accumulator. During the initial portion of the test a gradient of 5 pounds per square inch (psi) is imposed on the sample. One may find with low hydraulic conductivity geologic test materials there is a resistant low flow rate, therefore, the gradient may be increased later in the test program to 10 psi. During the breakthrough portion of the test, at least 2 pore volumes of fluid should be passed through the sample.

Determination of Effective Porosity

Based on the principles of Darcian flow, the velocity

(v) of a soluble constituent flowing through a porous medium can be estimated using the Equation 5-39:

$$v = Ki/n_e$$

where:

K is the hydraulic conductivity);

i = the hydraulic gradient, and,

n_e = the effective porosity.

For the purposes of calculating breakthrough velocity, breakthrough is defined as the point where the constituent concentration in the permeant leaving the sample is fifty percent of that entering the sample. The effective porosity is the porosity through which flow is actually occurring. As such, it is always less than or equal to the total porosity. The incorporation of effective porosity into the Darcy equation, then, takes into account bound water and closed voids within the sample.

Since it is typical for effective porosity samples under going testing have different values for hydraulic conductivity, it would be considered appropriate to examine the change in concentration of the constituent being measured in the permeant (in this case, chloride) leaving the sample in terms of the number of pore volumes of fluid passing through the sample. Since these small samples are relatively homogeneous, the ratio of the effective porosity to the total porosity is equal to the number of pore volumes passing through the sample at breakthrough. Values of effective porosity based on this method of analysis are shown in Table 5-9. The effective porosity obtained in the test series for glacial tills ranged from 0.26 to 0.34. (Golder 1987)

These values can be compared with work performed by Rawls, Brakensiek & Saxton (1982) on 1,323 soils with 5,350 horizons from 32 states that provided the total porosity, residual saturation, and effective porosity (among other soil properties) for this large spectrum of soil tests. Table 5-10 shows effective porosity for clay at 38.5%. This value is consistent with column tests performed in site investigations for clays.

5.6.8 Laboratory Hydraulic Properties Of Rocks

Samples for laboratory testing should be selected from available cores, and should be representative of site bedrock geologic units. Where possible, horizontal and vertical plugs of 25 mm diameter should be cut from drilled rock cores of 50–100 mm diameter. However, if the sample is friable and subject to breakup in handling, testing it may not be possible to measure hydraulic conductivity. The engineer should keep in mind that such laboratory

Table 5-9 Summary of Effective Porosity Results

Sample	Porosity	Pore Volumes at Breakthrough	Effective Porosity
TP-1	0.38	1.05	0.29
TP-3	0.38	0.68	0.26
TP-5	0.39	0.88	0.34
TP-9	0.38	0.88	0.33

procedures represent tests on core that is essentially so disturbed in terms of preservation of open discontinuities as to be of limited actual value.

Hydraulic Conductivity

The hydraulic conductivity of rock plugs can be measured in a standard gas permeameter, with nitrogen as the test fluid (API, 1966), with results empirically corrected for gas slippage and expressed for water at 20°C (approximate ground-water temperature in the field).

Effective Porosity, Bulk, and Matrix Density

The rock plugs or sample fragments may then be tested by the liquid resaturation method, employing propanol as the test fluid (API, 1966) in order to avoid a swelling reaction with any altered clayey materials, a situation that would lead to erroneous permeability determinations.

Pore-Size Distribution and Specific Yield

If the rock has exceptional porosity, further laboratory measurements can be undertaken on a smaller number of selected samples to investigate the distribution of pore-sizes and gravity-drainage characteristics.

When dealing with friable rock, the preferred method is by mercury injection porosimeter (Fatt, 1956). This technique involves forcing mercury into the pore spaces of the sample, progressively smaller pore necks being invaded at successively higher pressures, generating a curve of invaded pore-volume against injection-pressure.

The curves should be examined in detail to determine if an incomplete invasion of mercury has occurred. This could result from one of two reasons: either there exist many pores that are too small to be invaded, or some of the

Note: 1) Values in cells shaded in gray were calculated using the soil density relationships below.																					

Soil Density Relationships:

$$\gamma_{dry} = [(G_s \times \gamma_w) / (1+e)]$$

$$\gamma_{total} = [(G_s + Se) \times \gamma_w] / (1+e)$$

$$\gamma_{total} = \gamma_d \times (1 + (w\% / 100))$$

$$\gamma_{sat} = [(G_s + e) \times \gamma_w] / (1+e)$$

$$S\% = (w \times G_s) / e$$

$$n = e / (1+e)$$

$$e = n / (1-n)$$

	Porosity	Effective Porosity
Average	0.31	0.31 × 0.81 = 0.25
Minimum	0.26	0.26 × 0.81 = 0.21
Maximum	0.4	0.40 × 0.81 = 0.32

Dry Density Average = 118.4 pcf = 1,896.5 kg/m³

SUMMARY OF SENSITIVITY ANALYSIS RESULTS

Summary of Results - Sensitivity Analysis
Proposed Zion Landfill Site 2 North Expansion
Zion, Illinois

Sensitivity Analysis Run Number	Layer	Input Parameter Varied From Baseline	Justification	Baseline Value	Prediction Factor at the Zone of Attenuation ¹	Sensitivity Satisfactory?	File Name ²
1	High Density Polyethylene Geomembrane (HDPE)	Coef. Hydro. Disp. = 3.75E-05 m ² /yr	Increase by 25%	3.0E-05 m ² /yr	6.23E-07	Yes	Sens1
2	High Density Polyethylene Geomembrane (HDPE)	Coef. Hydro. Disp. = 2.25E-05 m ² /yr	Decrease by 25%	3.0E-05 m ² /yr	5.21E-07	Yes	Sens2
3	5-Foot Recompacted Cohesive Soil Liner	Coef. Hydro. Disp = 0.024 m ² /yr	Increase by 25%	0.019 m ² /yr	8.45E-07	Yes	Sens3
4	5-Foot Recompacted Cohesive Soil Liner	Coef. Hydro. Disp = 0.014 m ² /yr	Decrease by 25%	0.019 m ² /yr	3.27E-07	Yes	Sens4
5	5-Foot Recompacted Cohesive Soil Liner	Effective Porosity = 0.32	Site Maximum	0.25	5.88E-07	Yes	Sens5
6	5-Foot Recompacted Cohesive Soil Liner	Effective Porosity = 0.21	Site Minimum	0.25	5.67E-07	Yes	Sens6
7	Wadsworth Formation	Coef. Hydro. Disp = 0.024 m ² /yr	Increase by 25%	0.019 m ² /yr	5.63E-06	Yes	Sens7
8	Wadsworth Formation	Coef. Hydro. Disp = 0.014 m ² /yr	Decrease by 25%	0.019 m ² /yr	1.28E-08	Yes	Sens8
9	Wadsworth Formation	Effective Porosity = 0.32	Site Maximum	0.25	4.74E-07	Yes	Sens9
10	Wadsworth Formation	Effective Porosity = 0.21	Site Minimum	0.25	6.72E-07	Yes	Sens10
11	Wadsworth Formation	Thickness = 13.29 m	Site Maximum	10.27 m	3.60E-10	Yes	Sens11
12	Wadsworth Formation	Thickness = 6.00 m	Site Minimum	10.27 m	1.38E-03	Yes ³	Sens12
13	All Layers	Darcy Velocity = 3.08E-03 m/yr	Increased by an Order of Magnitude	Darcy Velocity = 3.08E-04 m/yr	1.48E-05	Yes	Sens13

Note:

1. The prediction factor is the value obtained at the base of the Wadsworth Formation prior to the zone of attenuation after 147 years for the respective sensitivity run.
2. Input and output files are saved with the same file root name but with different extensions - .in was used for input files and .ou was used for output files.
3. A surrogate model was run for the secondary minimum thickness which provided satisfactory results.

SENSITIVITY RUN #1
HDPE
COEF. HYDRO. DISP. = $3.75E-05$ m²/yr

Increase by 25%
